

The Dynamics of Venture Capital Contracts

Carsten Bienz^{a,c} and Julia Hirsch^{b,c}

August 2006

Abstract

We analyze the degree of contract completeness with respect to the staging of venture capital investments using a hand-collected German data set of contract data from 464 rounds into 290 entrepreneurial firms. We distinguish three forms of staging (pure milestone financing, pure round financing and mixes). Thereby, contract completeness reduces when going from pure milestone financing via mixes to pure round financing. We show that the decision for a specific form of staging is determined by the expected distribution of bargaining power between the contracting parties when new funding becomes necessary and the predictability of the development process. To be more precise, parties choose the more complete contracts the lower the entrepreneur's expected bargaining power - the maximum level depending on the predictability of the development process.

^cThis paper is part of a larger research cooperation between the Center for Financial Studies and KfW. It was presented at SITE-SSE (2004) Goethe University Frankfurt (2005), LSE (2005), Norwegian School of Economics and Business Administration, U Cambridge, U Aarhus, Queen Mary, RSM Rotterdam, U Exeter, U Amsterdam (all 2006) the GAEL-INRA Conference on Industrial Organization (2005), the Econometric Society World Congress 2005, the International Conference on Finance in Copenhagen, the 2005 meetings of the Verein für Socialpolitik, the Northern Finance Association and the 3rd RICAFA Conference (2005). It is scheduled for presentation at the 2007 AEA Meeting. We would like to thank the members of our respective PhD committees and Renée Adams, Eric Berglöf, Mike Burkart, Francesca Cornelli, Jess Chua, Antoine Faure-Grimaud, Stefanie Franzke, Guido Friebel, Mariassunta Giannetti, Christian Laux, Mario Pagliero, Per Strömberg, Uwe Walz, and Volker Zimmermann (KfW) for valuable comments. Finally, we would also like to thank all the KfW employees at KI for their support and especially Andreas Weber (KfW) for his help. All errors remain ours. Carsten Bienz gratefully acknowledges financial support by the German Research Foundation (DFG) and the German Academic Exchange Service (DAAD). Parts of this paper were written when Carsten Bienz was a visitor at the Financial Markets Group

1 Introduction

Traditionally, young innovative firms have difficulties in obtaining capital. Reasons are the high risk, the severe asymmetric information issues ex ante as well as the various moral hazard problems that come hand in hand with such an investment. As the venture capital industry succeeded in developing several mechanisms to cope with the above-mentioned problems, it has become essential for the financing of these firms¹. In this paper, we look at one major mechanism: staging.

Staging implies that not all the capital necessary to finance the project is paid out up front but in several tranches. The exact conditions for these tranches vary. To be more specific, staging can be designed in two different ways called round financing and milestone financing. Round financing means that every new tranche is negotiated separately when the venture needs further funding; milestone financing requires that exact contingencies which the firm has to achieve to obtain new funds are fixed in the initial contract. Therefore, the decision for one specific mode of staging is also a decision for or against more contract completeness which then determines the impact of renegotiation on future financing conditions.

Against this background, the aim of the present paper is twofold. First, we examine the determinants of staging in general. Second, we analyze the contracting parties' choice of one specific form of staging. We show that the probability of the use of staging per se is significantly higher for firms which are confronted with a higher degree of uncertainty and asymmetric information. The use of a specific form of staging, on the other hand, is determined by the expected distribution of bargaining power between the contracting parties when new funding becomes necessary and the predictability of the development process.

To our knowledge, there are only three important empirical studies on staging in the venture capital industry. First, Gompers [1995] looks at the structure of staged investments. He focuses on the determinants of funding size and funding duration for round financing but refrains from analyzing the determinants for one specific form of staging. The same is true for Kaplan and Strömberg [2003] and Kaplan and Strömberg [2004] who examine the determinants of the strength of both round and milestone financing separately. In this paper, we go beyond the existing empirical research by empirically modelling the choice of a specific form of staging. Thereby, we focus on the impact of renegotiation of future financing conditions on the initial contract design. We are not aware of other empirical papers testing this issue. However, Guasch et al. [2003] and Ricard [2005] present studies that focus on the decision for renegotiation given actual contracts. The former estimate a model of renegotiation for South-American procurement contracts while the

¹For a more detailed introduction to venture capital, see for example Gompers and Lerner [1999].

latter considers contract renegotiation in the Spanish movie industry. Thus our approach is complementary to theirs.

Moreover, the majority of the growing empirical literature on venture capital, including the three previously mentioned studies on staging, is based on US data. Important exceptions are, for example, Kaplan et al. [2006] whose study is based on a set of 23 countries, as well as Cumming [2002] and Bottazzi et al. [2004] for the European market. The most important exhaustive study for the German market is the one by Bascha and Walz [2003] that is based on survey data and analyzes security choice.

Against this background, the paper attempts to further reduce the existing gap in empirical research for venture capital industries outside the US by using a data set based on the German market. More importantly, in contrast to existing studies on the German market, the underlying data set exhibits unique characteristics. First, the data set (a proprietary one from Kreditanstalt für Wiederaufbau, KfW) constitutes a random sample of all portfolio firms which were financed by venture capitalists which, in turn, were supported by KfW in Frankfurt, Germany. As KfW is involved in a substantial part of all German venture capital investments, it is a representative sample of the German venture capital industry. Second, it covers both boom and bust periods as the data range from 1990 until 2004. Finally, contrary to the majority of empirical studies, the data set is not based on survey data but on information directly gathered from the contracts. To be more precise, it is based on all major documents concerning a specific deal, i.e. the business plan, the balance sheet, the term sheet, the shareholder's agreement, the investment memorandum as well as additional agreements.

The rest of the paper is organized as follows. The next section reviews the theoretical literature; the third section describes the underlying data set and presents descriptive statistics that characterize the venture capital industry in Germany. In the fourth section, we present empirical results. Section five concludes.

2 What Does Theory Tell Us?

In this section we summarize the theoretical literature related to staging proceeding in two steps: while the different forms of staging – milestone and round financing – are analyzed in subsection 2.2, in the next subsection we discuss the determinants of the decision for staging in general.

2.1 Why Do We Use Staging?

Staging implies that some of the funds deemed necessary for the firm to complete its project are withheld. This mechanism has three major implications.

First of all, as not all capital is provided up front, staging implicitly gives the investor the right to decide about the continuation or liquidation of the firm. This exit option for the investor saves resources because infeasible (negative NPV) projects are identified and liquidated early on (see Hellmann [1994]). Obviously, this advantage is the more pronounced the higher the ex ante uncertainty about the profitability of the project.

Second, in an asymmetric information context, staging can be interpreted as a signaling mechanism. Staged high quality firms face a low risk of liquidation in comparison with low quality firms whose liquidation risk is especially high. Thus an entrepreneur with private information about his firm's quality is able to use staging as a signal of firm quality. This issue is pointed out by Dessein [2005]. He models how a transfer of control to the investor serves as a signal of firm quality and congruence of objectives between the investor and the entrepreneur. This implies among other things that investor control should be increasing in the ex ante information asymmetry. One possibility of implementing investor control in this model is by short-term financing. However, short-term financing can also be interpreted as staging. Thus staging is the better, the higher the degree of asymmetric information ex ante.

Third, staging can act as a commitment device for the entrepreneur not to renegotiate the initial contract. This effect does not depend on the liquidation risk related to staging but rather on the fact that injecting less capital at the beginning of the relationship implies less sunk capital and consequently limited renegotiation possibilities for the entrepreneur. Neher [1999] models this mechanism. He shows that the entrepreneur cannot credibly commit to work and not to renegotiate if the venture has no collateral and the only asset is the entrepreneur's human capital itself. Furthermore, he points out that the hold-up problem can be solved by staging, as the stepwise provision of capital coincides with a gradual embodiment of the entrepreneur's human capital in the firm. Thus staging should be all the more advantageous, the more crucial the entrepreneur's human capital is for the success of the project and the less collateral, i.e. tangible assets, is available.

We summarize these arguments in the following hypothesis:

Hypothesis 1 *The higher the uncertainty, the higher the degree of asymmetric information, the more crucial the entrepreneur's human capital and the smaller the percentage of tangible assets, the more probable staging becomes.*

Staging, of course, has also serious shortcomings. First of all, staging may cause delays as entrepreneurs have to commit time to the negotiation process. This lag caused in implementing the project can induce additional costs such as retardation in the development process or in market entry, lost economies of scale or cost overruns. Certainly, these additional costs have to be outweighed by the benefits of staging. We think, however, that these costs can be disregarded, as they can be minimized by optimally structuring the

negotiation process.

Second, Cornelli and Yosha [2003] show that the entrepreneur may react to the prospect of early liquidation with an attempt to manipulate available information. This phenomenon called window dressing reduces the positive effects of staging and tends to be the more probable the softer the information available. This is exactly the case for firms for which the benefits of staging are the highest. Thus we cannot control for the underlying countervailing effects but only for the net effect of staging. This means that throughout all our tests concerning hypothesis 1, we will have to take into account that we only measure the net impact of staging.

Finally, staging also changes the entrepreneur's incentives. This impact is ambiguous: on the one hand, the liquidation risk increases the entrepreneur's incentives and, in turn, the project's overall probability of success. Wang and Zhou [2004], for example, show that the termination threat induces the entrepreneur to work harder in order to ensure further financing by the investor. Therefore, in their model, the effort level of the entrepreneur is always higher under staged financing. On the other hand, staging induces opportunistic behavior by the investor. This opportunistic behavior, in turn, reduces the entrepreneur's ex ante incentives. The negative incentive effect of staging must therefore be traded off against the above-mentioned positive incentive effect. This trade-off is analyzed by Rajan [1992], for example, who compares arm's length financing (i.e. upfront financing) and insider financing (i.e. staging). However, the extent of the negative effect crucially depends on the form of staging. Aghion et al. [1994] point out that the under-investment problem normally related to renegotiation (and therefore to staging) can be completely overcome by an adequate design of the renegotiation process². If this is the case – and if we interpret milestone financing as one example to prevent the under-investment problem, this is possible – the mentioned net incentive effect can never be negative and its size depends upon the form of staging. Consequently, incentive effects should not have an influence on the decision of staging per se but rather on the choice of a specific form of staging as we will show in the next subsection.

2.2 When Do We Observe What Form of Staging?

In the last section, we discussed the advantages and disadvantages of staging per se. However, some effects of staging, and among these especially the incentive effect for the entrepreneur, crucially depend on the form of staging which is chosen.

To be more precise, as shown above, there are two different forms of staging, namely

²They show that only two conditions must be fulfilled in order to guarantee an efficient outcome: first, the initial contract must specify a default option in case renegotiation fails and second, it must assign all the bargaining power to one party. The default option is determined by the initial contract, especially by the covenants which attribute specific rights to the investor in certain circumstances.

round financing and milestone financing. With round financing, every new tranche is negotiated separately when the venture needs further funding³. With milestone financing, the initial contract determines exact contingencies that the firm has to achieve to obtain new funds. Provided that the milestones are reached, the VC has the contractual obligation to release the funds to the firm⁴. Examples of such contingencies are the amount of revenues realized, the number of patents filed or the development of prototypes. Thus in this section, we analyze the disadvantages and advantages of these two forms in order to identify the determinants of a particular choice.

Firstly, milestone and round financing differ with respect to the degree of ex post flexibility and ex ante inefficiency. Whereas round financing offers more ex post flexibility, one obvious advantage of milestone financing is that it excludes renegotiation. Therefore, it prevents hold-up by the investor which eliminates the ex ante inefficiency caused by this. This solution mechanism is modelled by Nöldeke and Schmidt [1995], for example. In their model, the under-investment problem is overcome if the parties write a simple option contract that is very closely related to milestone financing: the entrepreneur has the right but not the obligation to exert certain effort levels and reach the specified milestones⁵. If the milestones are reached, the investor must pay out the next tranche of capital as determined in the initial contract. If the milestones are not reached, the default point is specified by the action chosen by the entrepreneur, i.e. the result achieved. If the difference between the two cases is larger than the entrepreneur's effort costs, high effort becomes worthwhile. So milestone financing is the more profitable, the more pronounced the negative incentive effect due to possible hold-up by the investor.

In a similar way, Bigus [2002] points out that the hold-up problem is the less pronounced, the smaller the loss of the entrepreneur when the relationship ends and a new investor must be found⁶. This means that the advantage of milestone financing increases with a decline in the entrepreneur's outside financing option.

Secondly, Cuny and Talmor [2004] raise another advantage of milestone financing, namely its greater ex ante flexibility. With milestone financing, one contract covers multiple states of the world simultaneously and thus claims need not to be priced fairly ex post but only ex ante, i.e. before knowing the outcome. This higher flexibility is especially valuable if there is a pronounced heterogeneity of beliefs between the contracting parties or if particular states require different incentive mechanisms.

³Thus no further funding is also an option.

⁴However, if any of the predetermined conditions are not met, no further funding will take place unless both parties negotiate new terms.

⁵Note that the exercise of any standard option contract is followed by a guaranteed delivery, while in our case some residual uncertainty is required because otherwise the moral hazard problem becomes irrelevant.

⁶He interprets his result by stating that the loss can be reduced by reinforcing patent protection so as to avoid idea stealing by the investor.

Thirdly, Cuny and Talmor [2004] also mention another possible disadvantage of milestone financing. Milestone financing promises the whole investment (contingent on milestones) ex ante whereas with round financing, there exists only a commitment to finance the current investment round. This means that the investor’s claim should be considerably larger under milestone than under round financing. If we assume pure equity financing, this implies a larger equity stake given to the investor and consequently, a smaller equity stake retained by the entrepreneur: the entrepreneur’s incentives are reduced. Thus the larger the total investment, the larger the negative incentive effect due to milestone financing. However, this is only valid with pure equity financing when the VC’s equity stake is fixed initially and any additional capital is paid into the firm’s capital reserves. Albeit this construct is found in practice, other constructs that avoid this problem are also frequently found. Thus the magnitude of this issue is not quite clear.

A further obvious, but extremely important caveat with respect to the choice of the different staging forms is the feasibility aspect: round financing and milestone financing must be implementable. As concerns round financing, it may cause prohibitively high contracting costs for very short time intervals creating a lower limit for the minimum duration of each round. The availability and enforceability of adequate milestones may be even more crucial. Even though this question has been largely ignored in the mentioned theoretical discussion, it is of extremely high empirical relevance. There are only a few studies that explicitly consider the nature of signals available and their relation to contracts. Repullo and Surez [2004], for example, look at the optimal capital structure with staging and the influence of signal availability on contract design⁷. To sum up these arguments, we can state the following hypothesis:

Hypothesis 2 *Given the feasibility of both staging forms, round financing compared to milestone financing should be the more probable, the better the entrepreneur’s outside financing option, the less pronounced the heterogeneity of beliefs between the contracting parties and the higher the total investment amount.*

3 The Data Set

3.1 Sample and Sample Selection Issues

Our analysis uses a proprietary, hand-collected data set from KfW based on contracts between VCs and their portfolio firms. KfW has a unique position in Germany’s venture capital market: being Germany’s largest promotional bank, it supports innovative firms by promoting the investment of the VCs. Although, as concerns our sample, KfW never directly invests in any of the portfolio firms, it becomes indirectly involved in the venture

⁷See section 4.2 and 4.3 for details.

capital deals in Germany. In order to obtain support from KfW, VCs had to apply by submitting the key details of their relationship with the portfolio firm, most notably, the term sheets, the business plans and the shareholder’s agreements. By providing us with access to these documents, KfW gave us the unique opportunity to collect detailed information on the relationship between the VC and its portfolio firm based on actual contract data.

In order to reduce the very time-intensive task of collecting detailed information from the numerous documents to a manageable size, we drew a random sample of 300 portfolio firms⁸. We categorized each portfolio company into one of three classes with respect to their investment date (before 1998, between 1998 and 2000, and after 2000) and eight classes with respect to the program or program combination through which their VC investor was supported by KfW. This categorization was undertaken with the objective of achieving a balanced representation of the population. Table 1 gives an overview of our sample and the support programs considered. Unfortunately, the data for 10 portfolio companies could not be evaluated. Therefore, our random sample finally consists of 290 portfolio companies that were financed in 464 investment rounds between 1990 and 2004.

We are confident that we do not have any major bias in the selection of our sample for two reasons. Firstly, as we were responsible for the sample selection process ourselves, we ensured that no selection bias occurred via the provider of all our documents (KfW) by drawing a random sample of all VC financed portfolio companies supported by KfW. Secondly, KfW supported a large proportion of the population of all investments realized by the German venture capital industry in the time period under consideration⁹. This means that we have a representative sample of the German VC industry. One obvious selection bias which we were not able to circumvent is the fact that we are concentrating on one particular geographic region (Germany) and the associated venture capital market. To a lesser degree this is true for the time period. We take all this into consideration by interpreting our data sample as the description of a situation of a young and evolving venture capital market.

As concerns the process of data collection, for each investment round, we evaluated the company’s balance sheet data and its business plan to get information with respect to the market position of the company and details about the financed project. Moreover, we took from the term sheet and the shareholder’s agreement detailed information about the security design, the timing, conditions and syndication of the investment, control and information rights of the venture capitalists and exit covenants. We translated this

⁸We drew this sample out of the population of all portfolio firms that were financed by venture capitalists which, in turn, were supported by KfW via one of the programmes mentioned in table 1.

⁹According to BVK (2003a) and (2003b), there were 11854 seed, start-up and expansion deals by its members in the relevant time period; KfW supported almost 7100 deals of potential members. This implies a market coverage of approximately 60%.

information into quantifiable variables. Finally, we complemented the data set with information about the venture capitalist supported by KfW. Overall, we gained a detailed picture of the control and information rights embedded in these contracts as well as of the characteristics of the entrepreneurial firm, the founder(s) and the VCs involved.

As usual in this type of study, we were confronted with the problem that all data were not always available. Thus the number of observations may vary depending on the variable studied. Typically, the amount invested and valuations were the most reliable variables whereas information on staging or investment memoranda were sometimes missing. Still, we do not see a systematic selection bias problem because there are several reasons for missing data. On the one hand, data may be missing for very young firms but, on the other hand, we often had also the most exhaustive term sheets for these firms.

3.2 Variable Descriptions

In what follows, we describe the data set in more detail and introduce the variables necessary for our regressions. Please note that all balance sheet data as well as exogenous factors such as the state of product development or the degree of asymmetric information is information that is known by the VC and the entrepreneur before they sign the contract.

Firm Characteristics

We have information about the project and the respective portfolio company. The variable AGE represents the age of the firm when the corresponding financing round is closed. Moreover, we observe the firm's industry: LIFE SCIENCES, INTERNET, IT/TELECOM, TRADITIONAL HIGH-TECH and OTHER INDUSTRIES are all dummy variables that indicate the project's industry. GROWTH INDUSTRIES is a dummy variable that indicates whether the firm is active in an industry with high growth potential, that is whether it corresponds to one of the three first mentioned industries or not.

Furthermore, we observe the firm's development stage in each financing round. First, we have information about the firm's development stage as defined by the German Venture Capital Association. We distinguish seed and start-up firms on the one hand, and expansion and later stage firms on the other hand: the dummy EARLY STAGE indicates whether the firm belongs to the first group or not. Second, we have balance sheet information from the year preceding the closing date of the corresponding financing round. We know whether the firm has any revenues (if this is the case, the dummy REVENUES takes value one) and we observe the fixed asset ratio (FAR) that indicates the ratio of fixed assets to balance sheet total¹⁰. Third, we have information about the firm's achievements.

¹⁰As we have many missing values in our sample, we adopt the following procedure. For all firms in a first financing round, with an age of less than one year and an investment phase of seed or early, we set

We know whether the firm has finished its product tests; whether it already has a finished product; whether the firm holds any patents or if it even has reference customers. We define a dummy named PATENTS taking value one if the firm holds any patents or its patents are pending when the financing round was closed. In addition, we construct two types of indicator variables that we deem necessary to test our hypotheses. First, we create a proxy for the degree of asymmetric information between both parties named AI. We think that the degree of asymmetric information heavily depends upon the amount of verifiable information that is available for the project. Thus we create a categorical variable by summing up four dummy variables which describe, in our opinion, essential steps in reducing information asymmetry: the dummy AUDITED BALANCE SHEET that indicates whether the balance sheet has been audited or not, the dummy FINISHED PRODUCT which signals the existence of a product, the dummy REFERENCE CUSTOMERS that indicates the existence of any reference customers and finally, the dummy BREAK EVEN that takes value one if the firm has reached its break-even point. While we could have included more factors in this definition, one problem we have is that we lose observations due to missing data. We thus strive for an optimal balance between measuring the degree of asymmetric information and data availability. For robustness considerations, we will in each case also run our regressions with the four individual dummy variables. Additionally, we define a variable which measures the relative degree of asymmetric information named RAI. This variable is aimed at correcting for the developmental aspect inherent in the AI variable. It is defined as the ratio of the degree of asymmetric information of the respective firm relative to the average degree of asymmetric information of all firms in the respective development stages (early stage, expansion, later stage). Second, we construct two measures that capture the current position of the firm in its development process: MARKET ENTRY takes value one if the firm has both a finished product and revenues. This proxy indicates that the introduction of the product in the market has successfully taken place. The dummy PRODUCT DEVELOPMENT takes value one if the product development process is just starting, i.e. if a finished product does not exist, there are no reference customers and product tests have not been successfully completed yet.

Finally, we observe whether the firm already received financing from banks or other VCs prior to the observed investment round. More concretely, we define a dummy OUTSIDE FINANCE that takes value one if the portfolio company has received bank, angel or other VC finance before the first round of VC financing we are looking at or if VC financing takes (or has taken place before) via a syndicate of different VCs. We think that both facts weaken the (lead) VC's informational advantage over other investors and thus

the fixed asset ratio to zero. If we lack information for higher rounds, we use the same ratio as in the round before. If this ratio is not available, we code both as missing values. Additionally, we do not resort to the preceding round in the case of second rounds where we coded the first round data to be zero.

ameliorate the entrepreneur's outside financing option.

VC, Entrepreneur and Investment Characteristics

Second, we have information about the VC, the entrepreneur and the investment characteristics. We classify each VC according to his type into three categories named INDEPENDENT VC, PUBLIC VC and OTHER VC. The latter category includes both bank-dependent and corporate VCs¹¹.

Moreover, we have information about the entrepreneurs running the portfolio firm. We know if any of the founders has a PhD or higher degree of education (then, the dummy variable RESEARCH DEGREE takes value one), we observe whether any of the founders has a background in engineering or natural sciences (in this case, the dummy variable SCIENCE BACKGROUND takes value one) and we know whether we face a repeat entrepreneur, i.e. someone who has already run a firm (this is captured by the dummy variable REPEAT ENTREPRENEUR). In order to account for the value of the entrepreneur's human capital within the firm, we construct the variable E EXPERT. As we know that the entrepreneur's role is crucial for the technological development of the product, we take into account both the qualification of the entrepreneur and the need of expertise by the firm when constructing the variable. More concretely, the variable takes value one if the firm belongs to a high-tech industry, the firm does not have a finished product (i.e. the firm strongly needs the entrepreneur's contribution) and if the entrepreneur holds a research degree (i.e. the entrepreneur is highly qualified).

Finally, we have information about the investment itself. We observe the year when the financing round is closed and define three time dummies. PERIOD 1 takes value one if the financing round is closed during the early period of relatively low venture capital activity, namely before 1998, PERIOD 2 if it is closed during the boom, i.e. between 1998 and 2000 and PERIOD 3 if it is closed after 2000 – a period of relative decline and reorganization of the venture capital industry. In addition, we observe the total amount invested, the financing instrument used and the timing of the investment. In order to control for the total amount of capital necessary to finance the project, we construct a further proxy variable. We assume that each firm's balance sheet has to reach a certain minimum threshold before the firm can be taken public. This size is the average balance sheet of all firms in Germany's "Neuer Markt" prior to their IPO in the five mentioned industries¹². The variable EBS (expected balance sheet) is then defined as the difference between the average balance sheet of the public firms in the respective industry and the current balance sheet of the firm we are studying and is normalized by the average balance

¹¹We also include the business angels in our sample in this category.

¹²We thank Stefanie Franzke for giving us access to her data on IPOs on the "Neuer Markt".

sheet¹³.

Staging: Definition and Measurement

As the aim of this paper is to analyze the determinants of staging and its different forms, it is important to exploit all the available information related to staging. Therefore, in a first step, we define a dummy variable, named STAGING, that takes value one if the project is financed in several steps, and zero otherwise. This means that STAGING takes value one whenever one of the different staging forms can be observed. These are represented by two dummy variables: ROUND takes value one if staging is done in several independent rounds and MILESTONE if future capital is contingent on specific known milestones.

To be more precise, the variable MILESTONE takes value one if at least 20% of the investment is dependent on the achievement of predefined milestones. The variable ROUND takes value one whenever we observe a further financing round. Additionally, it takes value one when we know that the current round does not finance the project until its break-even¹⁴. The latter information is taken from the VC's investment memoranda. This construction has two important implications. First, we even have information about the most recently financed projects which allows us to circumvent two major econometric problems: truncation and autocorrelation between the financing rounds. Second, we may be confronted with an overestimation of the probability of round financing as the above definition also includes rounds where staging was not expected from the beginning but occurred nevertheless. The problem we faced was that it is quite difficult to distinguish whether further financing rounds were really unexpected or were just not mentioned in the original contract. On the other hand, we may be confronted with an underestimation of the probability of round financing for more recent projects as a further financing round may have been planned even if the project has already reached its break-even. In order to check our results for robustness with respect to this definition, we also run our regressions in part 4.1 for alternative definitions of ROUND. First, we define ROUND as taking value one only if a subsequent financing round is actually observed. Second, we let ROUND take value one only if it is not expected that the current financing round finances the project until its break-even. Finally, we run our regressions with the original definition of ROUND for first rounds only.

We also define three subcategories: PURE MILESTONES, PURE ROUNDS and MIXES. PURE MILESTONES takes value one if milestone financing occurs and we know that no

¹³For around 20 firms we observe this value to be negative. Our theory says nothing about these types of firm. Therefore, we coded them as missing values in our regressions.

¹⁴Moreover, if we do not observe a subsequent round and we do not know whether the current round finances the project until its break-even or not, we recur to a variable which indicates whether round financing takes place. The problem with this variable is that we cannot distinguish whether only past rounds or also future rounds are planned. That is why we do not use this variable exclusively.

round financing takes place. Analogously, we define PURE ROUNDS. MIXES takes value one if we know that milestone and round financing are used simultaneously. Finally, we consider four categories of milestones: financial milestones, product milestones, firm specific (other) milestones and different mixes of these types of milestones.

3.3 Descriptive Statistics

In the following we want to give a more detailed overview of the sample. Therefore, in a first step, we present some basic descriptive statistics. The average amount invested per financing round is about 5.4 million euros and the portfolio companies are on average 5.08 years old when they receive VC financing for the first time. The medians are considerably smaller (1.3 million euros and 2 years), an indication of outliers. At this point, one can already infer that the percentage of early stage financing is quite high in our sample. Indeed, 72.8% of the financing rounds correspond to early-stage financing whereas only 27.2% of the financing rounds are related to expansion and later stage firms¹⁵. The portfolio companies are active in a broad range of industries: 20.7% in the field of life sciences, 36% in the sector of IT, telecommunications and software development, 9.7% belong to the internet sector, 19.6% are active in traditional high-tech industries and 14% could not be classified in either of these sectors but are active in rather less R&D intensive branches.

Second, we want to characterize the different types of financial instruments used (see table 3). As a broad range of different combinations of financial instruments achieves the same allocation of cash-flow and control rights, it is important to analyze these instruments properly. Therefore, we classify each financial instrument used in a single financing round according to five characteristics: upside cash flow rights, downside protection, change of control, cash flow rights at exit and voting rights. This classification procedure allows a better interpretation of the securities used and guarantees better comparability. In a second step, we distinguish four main categories (pure equity, pure debt¹⁶, debt-equity mixes and convertibles) and nine subcategories. Thereby, the more detailed classification takes into account the existence of liquidation preferences or the extent of the debt component in debt-equity mixes. We see that whereas debt and different types of equity play an important role (23 % and 29% respectively), debt-equity mixes are the most frequently used type and occur in 38% of all financing rounds. Only 8% of all firms are financed by convertible instruments.

Last but not least, table 2 describes the observed staging behavior in our sample. Staging is used in 70% of the analyzed observations; pure rounds are used most frequently (59%), followed by mixes (24%) and pure milestones (17%). There also seem to be differ-

¹⁵These percentages refer to the financing rounds for which we have available data for the respective criterion.

¹⁶Debt is actually subordinated debt, thus it is only senior to the equity in the firm.

ences in the staging behavior across time and VC types. As shown in table 2, there is a slight decline in the use of staging during the boom period – this may be attributed to the reduced bargaining power of the VCs due to the high amounts of capital chasing few deals in that time period – and an increase in period 3 slightly beyond the level of period 1. Interestingly, when looking at the different staging forms, we recognize more pronounced changes. While in period 1 only 7% of staging is in the form of pure milestones, 7% is in the form of mixes and 86% is in the form of pure rounds, the composition changes dramatically in the third period: staging in the form of pure milestones increases up to 24%, staging in the form of mixes increases to 29% and staging in the form of pure rounds decreases to 47%. As concerns the behavior of the different VC types, we see pronounced differences in both the implementation of staging per se and the use of the different forms of staging. On the one hand, independent VCs use staging more often than other VC types which in turn use staging more often than public VCs. On the other hand, independent VCs use rounds in more than half of all staged firms, but use relatively more mixes than pure milestones; public VCs use rounds in more than half of all staged firms, but they use relatively more pure milestones than mixes; and finally, other VC types use rounds in 77% of the cases and, similarly to public VCs, they use more pure milestones than mixes.

4 Empirical Evidence

4.1 The Determinants of Staging

We begin by evaluating hypothesis 1 that refers to the determinants of the staging decision. In a first step, we discuss the instrumentalization of this hypothesis before presenting the descriptive statistics and the results of the univariate probit models. We conclude by discussing the robustness of our results and their implications.

Instrumentalization of the Hypothesis

Hypothesis 1 can be divided into two parts. The first part states that the higher the uncertainty and the higher the degree of asymmetric information, the more probable is staging. The second part refers to the positive causal relationship between the importance of the entrepreneur’s human capital and the staging decision. Therefore, our empirical strategy can be based on the following model:

$$\text{Staging}_i = f_i(\text{Uncertainty, Asym. Info, Extent of Hold-up by the E, Controls}) + \epsilon_i,$$

where

$$\text{Staging}_i = \begin{cases} 1 & \text{if firm } i \text{ is staged} \\ 0 & \text{if firm } i \text{ is not staged} \end{cases}$$

Finding adequate controls is relatively straightforward: we will include time as well as VC dummies and we will additionally control for industry effects by including four of our industry dummies. In contrast, differentiating between uncertainty, asymmetric information and the firm’s development stage per se poses a relatively large challenge. Several potential indicator variables capture different aspects of uncertainty and asymmetric information such as the firm’s age, the early stage dummy, the revenue dummy or the AI variable¹⁷. However, none of these variables captures all the different facets of uncertainty and asymmetric information and all of them include a “developmental aspect”. This means that all indicator variables compare the firms along their development path but not from a cross-sectional perspective. Unfortunately, such a cross-sectional view cannot be implemented for the majority of these variables¹⁸. We try to cope with this limitation for the AI variable by using the RAI variable instead. However, this variable must be handled with precaution as its components do not vary much across the development stages of the firm. This means that the differences between the firms of one comparison group (e.g. all early stage firms) are quite small resulting in a relatively low information content of the variable.

Thus we face a set of possible proxy variables that are quite heterogeneous in the economic effects they capture but are certainly not mutually exclusive as they are partial substitutes for each other. This view is also reconfirmed by the correlations of these variables (see table 5). As we face the econometric problem that we cannot include all proxies simultaneously in the regression, because of their correlation, we run the same standard specification for each proxy variable separately to ensure the robustness of our findings. Moreover in order to control for the extent of the entrepreneur’s hold-up potential, we include our different human capital variables as well as the fixed asset ratio. However, as the human capital variables are partially highly correlated with the mentioned proxy variables for uncertainty and asymmetric information, we run the regressions in a first step without including the human capital variables and only in a second step, we include them together with the proxies where possible.

Descriptive Results

The descriptive results are shown in table 4. As we can see, the descriptive statistics broadly confirm the first part of hypothesis 1: staged firms are significantly younger, have revenues less often, are more probable to be early-stage firms and exhibit a higher degree of asymmetric information. In fact, all four components of AI (AUDITED BALANCE SHEET,

¹⁷Note that these variables are indeed suitable to control for the mentioned aspects because further characteristics of older firms which are crucial in other contexts – like the availability of internal funds – are irrelevant for the large majority of firms in our sample.

¹⁸Because the developmental aspect is completely inherent in these variables.

FINISHED PRODUCT, REFERENCE CUSTOMERS, BREAK EVEN) significantly differ between staged and non-staged firms. Interestingly, the means of the RAI variable do not significantly differ between staged and non-staged firms. This implies that developmental aspects seem to play a crucial role. Though, given the above-discussed limitations of our RAI variable, this result does not mean that “pure” asymmetric information problems are irrelevant.

The second part of hypothesis 1 is only partly confirmed. Table 4 shows that neither the fixed asset ratio nor the majority of the human capital indicator variables significantly differ between staged and non-staged firms. Only the research degree dummy is significantly higher for staged firms.

Finally, there are several control variables which differ significantly. There are significantly more life-science and internet firms and significantly fewer traditional high-tech firms and firms of other industries among the staged firms. This may be explained by the fact that the former industries are related to a higher degree of uncertainty or to the fact that they are more research-intensive and that therefore the entrepreneur’s human capital is more important. Moreover, there are significant differences with respect to the time periods and the VC types.

Regression Results

In this subsection, we present the results for hypothesis 1 based on univariate probit regressions with error terms clustered at the firm level. The results corresponding to the first part of hypothesis 1 can be found in table 6. We find broad support for this first part, namely the impact of uncertainty and asymmetric information. More specifically, as outlined in subsection 1, we successively include all our different proxy variables and get the following results: AGE is negative and significant at the 5% level, showing that the older the firm, the less probable staging becomes; EARLY STAGE is positive and significant at the 1% level indicating that the probability of staging is 19% higher for early stage firms; and finally, REVENUES is negative and significant at the 5% level. This means that the probability of staging is less for firms with revenues. In order to emphasize the asymmetric information aspect, we use the categorical variable AI. The coefficient is significant at the 1% level: the higher the degree of asymmetric information the more probable staging becomes. Using the components of AI on an individual basis yields further insights: in fact, the result seems to be driven by only one component of AI, namely BREAK EVEN which is significant at the 1% level. This confirms the fact that developmental aspects seem to play a predominant role. In order to blind out this aspect and focus on “pure” asymmetric information, we subsequently include RAI in our regression: the coefficient is insignificant, however. We also get an insignificant coefficient

for the expected sum of funding still necessary to take the firm public (EBS)¹⁹.

It is also interesting to have a look at the control variables. Surprisingly, both the control variables for the different VC types and for the time periods are insignificant. The picture is different for the industry proxies though: LIFE SCIENCES, IT/TELECOM and INTERNET are positive and broadly significant. This can be explained by the fact that firms in these industries have a higher growth potential, a higher degree of uncertainty and a higher need for the entrepreneur's contribution to the firm.

To test the idea of the entrepreneur's importance to the firm explicitly, we run several additional regressions (see table 7). In a first step, we include E EXPERT (variant a) and, in a second step, the three different dummy variables concerning the entrepreneur's human capital (variant b): REPEAT ENTREPRENEUR, SCIENCE BACKGROUND and RESEARCH DEGREE. We run each variant for three different specifications. First of all, we include the fixed asset ratio in order to test our hypothesis. Whereas the fixed asset ratio is not significant in the first variant, it is significant at the 10% level in the second one. This result is not robust to the inclusion of AGE, for example. We then run the regression with two of our proxy variables (AGE, EARLY STAGE)²⁰. It turns out that while our proxy variables continue to be highly significant, neither E EXPERT nor the individual human capital variables are significant. These results also hold when including the fixed asset ratio, our proxy variables as well as the human capital variables simultaneously.

Finally, we do robustness checks with respect to our staging definition. First, we also run the above regression for first rounds only and second, we define two new dummy variables for staging taking into account our alternative definitions of round financing. It turns out that our results are broadly confirmed: all our proxy variables for uncertainty and asymmetric information continue to be highly significant and the human capital variables as well as the fixed asset ratio continue to be insignificant. Only with the second definition of round financing (considering exclusively the information whether the current financing round finances the project until its break-even or not), the fixed asset ratio as well as RESEARCH DEGREE become significant. In this case, our regressions also confirm the second part of hypothesis 1 underlining that the lower the fixed asset ratio and the more important the entrepreneur's human capital, the more probable staging is. These last results should be handled with precaution, however²¹.

To conclude, we can say that the regression results are in line with the descriptive

¹⁹Interestingly, the coefficient turns out to be highly significant when coding the negative values as zeros. The same is true for the means which differ at the 5% significance level. The result should be handled with precaution, however, as these "unclassifiable" observations may be the driving force. Therefore, further research is necessary at this point.

²⁰Note that AI and RAI as well as REVENUES are highly correlated with the human capital variables so that we cannot include them in our regressions.

²¹For the sake of brevity, we omit the corresponding tables here. Of course, they are available upon request from the authors.

statistics. They confirm the first part of hypothesis 1 which states that the higher the uncertainty and the higher the degree of asymmetric information, the more probable is staging is. Just as in the t-tests, all our proxies are highly significant in each specification of our regressions. Note, however, that our variables are not able to attribute the decision for staging to “pure” asymmetric information aspects only, as developmental aspects seem to matter, too. The importance of the entrepreneur’s human capital, on the other hand, is partly confirmed by RESEARCH DEGREE in our descriptive statistics and our robustness tests, but otherwise none of the human capital variables is significant in the regressions. The same is true for the fixed asset ratio. Thus the second part of hypothesis 1 which states that staging should be the more probable, the more important the entrepreneur’s human capital and the less tangible the assets is not confirmed by our data. This result as well as the result concerning the asymmetric information aspect should be handled with precaution, however, due to the high amount of missing values as well as the limitations of our indicator variables.

Discussion

Apart from staging, there are further potential contracting elements with a similar impact. Especially debt grants the VC an exit option or can be used by the entrepreneur as a signaling device just as staging can. Even though we focus our analysis on the determinants of the decision for staging and not on substitutabilities and complementarities between different instruments, it is important to check that our results are not driven by the underlying relationship between staging and debt.

However, we cannot directly include a debt variable in the above regressions because debt would be an endogenous variable. It is a contractual element just like staging and thus its use is determined simultaneously with staging. In order to cope with this disadvantage and at the same time do justice to possible substitutability effects, we run robustness checks for our previous results by splitting our sample into one part that includes all observations that have a strong debt component and a second part with all observations that do not have a strong debt component. A strong debt component means pure debt, nonstandard debt or convertibles of the subcategories “US style” or “mixes” (see table 3). For these securities, the dummy DEBT COMPONENT takes value one. We find that the determinants for the staging decision are broadly confirmed for each of the two subsamples²².

The major differences are the following. As concerns the descriptive statistics, the time and industry effects which we find for the complete sample, seem to arise almost exclusively from the observations with a strong debt component. The same is true for AU-

²²Again, for the sake of brevity, we omit the relevant tables here. Of course, they are available upon request from the authors.

DITED BALANCE SHEET. On the other hand, the significant difference of RESEARCH DEGREE can only be confirmed for the observations without a strong debt component. In addition, the fixed asset ratio turns out to be important for the subsample of observations with a strong debt component although it is neither significant in the subsample of observations without a strong debt component nor in the complete sample. This result is also confirmed in the regressions. Whereas all our proxy variables differ significantly in the descriptive statistics, in the regressions, this is not the case anymore: whereas EARLY STAGE continues to be highly significant in both subsamples, AGE loses its significance for the subsample of observations with a strong debt component (the sign continues to be correct). The reverse is true for BREAK EVEN. AI loses its significance in both subsamples but the sign continues to be negative. With respect to the human capital variables, we do not get any robust results in any of the two subsamples. The regression results must, however, be handled with precaution due to the limited number of observations. To sum up, we get evidence that the determinants of staging do not change fundamentally when splitting our sample into two subsamples according to the use of a strong debt component or not.

In addition, it is interesting to compare our results on staging to the results found in the papers based on US data. As mentioned above, Gompers [1995] as well as Kaplan and Strömberg [2003] and Kaplan and Strömberg [2004] consider staging in their studies. Gompers [1995] shows that the younger the firms, the stronger the staging effect is, i.e. less capital is released to the venture and funding duration is shorter. This is broadly in line with our findings: staging is more probable for younger firms. Kaplan and Strömberg [2003] find that round duration is longer for repeat entrepreneurs, while Kaplan and Strömberg [2004] show that round duration increases according to the degree of external risk, while the amount of funding that is contingent increases with internal risks. Both findings are again broadly in line with our findings: staging is more probable for firms with higher risks. Thus, we can say that our data reflects the typical characteristics of US data sets with respect to staging as the staging behavior per se does not seem to differ significantly.

To conclude this subsection, the results are quite robust and in line with the existing empirical research: we find that the decision for staging is determined by the degree of uncertainty and asymmetric information the investor is confronted with. Throughout all our regressions, the proxy variables AGE, EARLY STAGE, REVENUES and AI are highly significant. The relative degree of asymmetric information is never significant, however. The same is true for the expected investment amount. With respect to our human capital variables, we get mixed results. Whereas the descriptive statistics partly point out such an effect, it is not reconfirmed in the regression results. As mentioned above, these last

results should be handled with precaution, however, due to the limitations of our proxy variables.

4.2 How Does Milestone Financing Work?

As mentioned above, the existence of suitable signals is a crucial prerequisite for the use of milestone financing. This is in strong contrast to round financing which does not call for a contingent contract to be feasible. Thus before analyzing the decision between the different staging modes in more detail in the next section, we want to investigate the specifics of milestone financing.

The essential requirement for milestone financing is – as mentioned – the existence of suitable milestones which must be able to describe the expected development of the firm in the future. Therefore, the specific type used should heavily depend on the development stage of the firm. We distinguish four different categories of milestones in our data set: product milestones such as the completion of a prototype or satisfactory product tests, financial milestones such as a minimum sales level or other (firm specific) milestones. One typical example of these other milestones is the hiring of a specific type of manager but this category comprises a broad range of different milestones. Finally, we classify all mixtures of different milestone types as a separate category.

The descriptive statistics for the different kinds of milestones can be found in table 9. These descriptive statistics give us first insights that product and financial milestones seem to be used in successive development stages. We observe that product milestones (in comparison to all other types of milestones) are used more frequently with a higher absolute and relative degree of asymmetric information, for firms which are about to start their development process and for which the entrepreneur’s human capital is crucial. As opposed to this, product milestones are used less often with firms which have already entered the market, which have a finished product, reference customers and have reached break-even. By comparison, financial signals are more frequently used with a lower degree of asymmetric information, in firms with reference customers and in which the entrepreneur’s human capital is only of marginal importance. These results are also confirmed by our univariate probit regressions which we run with each milestone dummy as an independent variable. In table 10, we see that both AI and RAI as well as PRODUCT DEVELOPMENT are significant in the probit regressions for product milestones. This strengthens our result that product milestones are rather used for firms in very early development stages, i.e. for firms for which the product development is the main challenge. By contrast, concerning the regressions with FINANCIAL MILESTONE as an independent variable, we find that AGE, AI, and REFERENCE CUSTOMERS are positive and significant whereas PRODUCT DEVELOPMENT is negative and significant. This, in

turn, underlines our descriptive statistics stating that financial milestones are used with more developed firms as only for these kinds of firms do financial statements become really meaningful.

The remaining two milestone type categories, namely other firm-specific milestones and mixes, seem to be used in quite heterogeneous cases. The only variables that are significant in the regressions (see table 11) are the following: for other milestones, the `PRODUCT DEVELOPMENT` is negative and significant. This shows that if the firm is about to start its product development process, other milestones are used less frequently. This result is intuitive as product signals are certainly optimal in this case. The same insights can be derived from our descriptive statistics, too. Interestingly, the mean of the expected investment amount is significantly higher for other milestones relative to all other types of milestones: firms that need more funding to complete their project are more inclined to use firm-specific milestones. As concerns signal mixes, we do not get any robust results either in the descriptive statistics or in the univariate probit regressions. Mixes seem to be used in quite heterogeneous cases which we are not able to identify given our data.

It is furthermore interesting to see whether the use of specific milestones differs between mixes and pure milestone financing. In table 8, we observe that product milestones are used significantly more with mixes than with pure milestone financing; that there is not a significant difference in the use of financial and other milestones; and that milestone mixes are used more with pure milestone financing than with mixes (though the difference is only significant at the 11% level). In subsection 2.2, we noted that adequate milestones must be available for the whole development process in order to be able to implement pure milestone financing. As product milestones cover only the first part of the development process, it is clear that they should be used more often with mixes than with pure milestone financing. As financial and other milestones are used for more advanced firms, they can, in principle, describe the remaining development process. This implies that there should not be a significant difference in the use of financial and other milestones between the two forms. The difference in the use of milestone mixes may be explained by two facts: one the one hand, if suitable milestone mixes can be defined, such a mix is able to cover the whole development process; on the other hand, it is quite costly to define a mix of different milestones. Thus it is clear that milestone mixes are indeed observed more often with pure milestone financing than with mixes.

To conclude, our data gives us first insights with respect to the use of different milestone types. We find that product and financial milestones are used in successive development stages and that the availability of milestones seems to be important when choosing one form of staging or another.

4.3 The Determinants of the Different Forms of Staging

In this last section, we analyze the determinants of the choice of one of the different forms of staging by testing hypothesis 2. Once we look at the data, a major problem arises: in contrast to the theoretical discussion that focuses on the differences between round and milestone financing, we additionally observe mixes of these two forms. Therefore, in a first step, we attempt to explain the appearance of mixes and reinterpret hypothesis 2 from this new perspective. Moreover, we have to discuss the instrumentalization of this hypothesis. In a second step, we present descriptive results before running multinomial probit models in order to identify the determinants of the use of the different staging forms. The section concludes with a summary of our results.

Instrumentalization of the Hypothesis

Hypothesis 2 states that given the feasibility of both forms of staging, round financing relative to milestone financing should be the more probable, the better the entrepreneur's outside financing option, the less pronounced the heterogeneity of beliefs between the contracting parties and the higher the total investment amount. In order to test this hypothesis, adequate proxies for the entrepreneur's outside financing option and the heterogeneity of beliefs between the contracting parties as well as the total investment amount are necessary. Moreover, we have to instrumentalize the feasibility aspect what will allow us to explain the appearance of mixes.

As concerns feasibility, one has to distinguish between the feasibility of milestone financing and the feasibility of round financing. As concerns the feasibility of milestone financing, the crucial prerequisite is the availability of adequate milestones. This implies – as suggested by our results on the characteristics of milestone financing – that for very early stage firms, pure milestone financing may not be feasible because adequate milestones can only be defined for the near future and not for the whole development process. In this case, round financing is always necessary to implement staging. Then mixes between milestone and round financing may act as a second-best choice to overcome the negative effects of potential hold-up by the VC. This is due to the fact that with mixes in comparison to pure rounds, a new financing round only becomes necessary later on once more reliable information exists. Still we have to bear in mind that while ex ante flexibility is also increased, ex post flexibility is reduced when using mixes. This means that mixes relative to pure rounds should be used the more often, the worse the entrepreneur's outside financing option and the more pronounced the heterogeneity of beliefs between the contracting parties. If pure milestone financing is feasible, i.e. if we are confronted with more advanced firms, all three staging modes can be chosen and the decision depends on the trade-off between the negative incentive effect and ex post flexibility. We conjecture

that the heterogeneity of beliefs aspect should not play a crucial role anymore as milestone financing is only implementable for relatively advanced firms (see below for details). Thus, milestone financing with respect to pure round financing and mixes should be observed the more frequently, the more advanced the firm is (i.e. the more probable it is to find adequate milestone for the whole development process) and the worse the entrepreneur's outside financing option.

With respect to the feasibility of pure round financing, we mentioned in subsection 2.2 that because of prohibitively high contracting costs, each round may have to cover a minimum length. If this is the case with pure round financing, the effect of staging is less pronounced than with pure milestone financing: negative NPV projects may be abandoned only relatively late, for example. Consequently, a strong staging effect can be implemented solely by pure milestone financing or mixes between rounds and milestones. If we assume that for firms with a high degree of asymmetric information and uncertainty, a strong staging effect is more desirable, either pure milestone or mixes should be used with these firms. In this case, mixes may act as a second-best alternative to reduce the loss of ex post flexibility, i.e. pure milestone financing relative to mixes should be used the more often the worse the entrepreneur's outside financing option is and the more pronounced the heterogeneity of beliefs between the contracting parties are. For more advanced firms, for which pure round financing is also desirable, all three modes of staging should be possible. Again, we conjecture that the heterogeneity of beliefs aspect should not play a crucial role anymore for these relatively advanced firms. Thus we expect that round financing relative to pure milestone financing and mixes should be observed the more often the more advanced the firms (i.e. for firms for which a strong staging effect is no longer crucial) and the better the entrepreneur's outside financing option.

In order to test these two alternative interpretations of our hypothesis, we need suitable proxy variables for the entrepreneur's outside financing option and the degree of heterogeneity of beliefs.

With respect to the entrepreneur's outside financing option, we conjecture that both the information available when conditions are renegotiated as well as (previous) contacts with other investors besides the VC may play a crucial role. If the VC, as an inside investor, refuses to continue to fund a project, this is a negative signal for outside investors. Thus the entrepreneur has to convince possible investors of the profitability of his project. Therefore, he needs credible, hard information. This means that the degree of asymmetric information must be relatively low. In addition, in an advanced development stage, the firm has already established a relatively long track record. This, of course, may also help to ameliorate the entrepreneur's outside financing option. On the other hand, if the project was or is financed by financial intermediaries other than the (lead) VC (banks, syndicating

VCs, angels), the entrepreneur’s outside financing option is better as he may also resort to these (former) inside investors for new funding.

With respect to the heterogeneity of beliefs between the contracting parties, we conjecture that it should be the more pronounced the higher the degree of asymmetric information and uncertainty, because then no objective evaluation criteria exist and it is more probable that each contracting party holds its own expectations about the future. For example, entrepreneurs naturally should be more optimistic than VCs. However, as soon as hard facts are available about the profitability of the project, beliefs should become less subjective and therefore more homogeneous.

In order to reflect the above-mentioned ideas, we use different indicator variables for the development stage of the firm (PRODUCT DEVELOPMENT, MARKET ENTRY), the degree of asymmetric information (AI, its single components and RAI to reduce the developmental aspect), the tangibility of assets (FAR) and the existence of further investors (OUTSIDE FINANCE).

In order to further test the argument put forward by Cuny and Talmor [2004] about the influence of the total investment sum, we use the expected balance sheet EBS as a proxy for the total investment size. Finally, we use E EXPERT as a proxy variable for the importance of the entrepreneur’s human capital, because we expect the negative incentive effect of potential hold-up by the VC to be the more harmful the more important the entrepreneur’s contribution.

Descriptive Results

We start by comparing the means of firms that use pure milestones to those that use pure round financing. The summary statistics are given in table 12. We observe that firm characteristics do not play any significant role. This may be explained by the fact that the mentioned feasibility problems are both relevant and that there are, therefore, no significant differences. But we observe that the expected funding needs (EBS) are significantly higher with milestones. This contradicts the argument by Cuny and Talmor [2004] that milestone financing should be used less often with higher investment amounts, because it reduces the entrepreneur’s incentives. The result should be handled with precaution because of the limitations of our variable²³. However, the result can also be interpreted from a different angle: when the entrepreneur’s financing needs are relatively large, he crucially depends on the subsequent injection of funds. This implies that it should be more difficult to find an outside investor due to the relatively high amount of funding necessary, i.e. to his relatively bad outside financing option. This argument is further underlined by the significant difference in the means of OUTSIDE FINANCE. In addition, there are both VC

²³The variable where we coded the negative values as zeros also turned out to be insignificant.

and time effects.

The decision between pure milestone financing and a mix of milestone and round financing, on the other hand, is influenced by firm characteristics. If the degree of asymmetric information decreases, pure milestone financing becomes more probable than mixes. The same is true for RAI. In addition, the means of different variables that proxy for the development stage of the firm differ significantly, indicating that milestone financing is rather used with more developed firms. See, for example, PRODUCT DEVELOPMENT, MARKET ENTRY, FINISHED PRODUCT as well as REVENUES. This supports the assumption that the foreseeability aspect is crucial: pure milestone financing can only be implemented for more developed firms for which adequate milestones can be defined²⁴. At the same time this means that the contracting cost argument is not the crucial limiting factor as otherwise pure milestone financing should rather be used for less advanced firms. On the other hand, we find evidence for the impact of the hold-up problem on the choice of one of these two forms of staging. First, the mean of the expected funding needs (EBS) is significantly higher for pure milestone financing. This underlines again that the outside option of the entrepreneur is the worse, the higher the funding needs are and thus, milestone financing is more advantageous. Second, the mean of OUTSIDE FINANCE is significantly lower for firms that use milestone financing: mixes are used more frequently when other financial intermediaries than the (lead) VC are or were involved in the firm. Then the outside financing option of the entrepreneur is better and so the negative impact of round financing decreases. Finally, there are VC type effects.

In a last step, we consider the decision between pure round financing and mixes. We see that the mean of PRODUCT DEVELOPMENT is significantly higher for mixes than for pure round financing. The same is true for E-EXPERT as well as its component RESEARCH DEGREE. Consequently, a firm at an earlier development stage, which is confronted with a higher degree of uncertainty and for which the entrepreneur's human capital is crucial, tends to use more mixes than pure round financing²⁵. This result can be explained in two different ways: first, it may be a sign that the contracting cost argument is also valid as round financing is rather used for more advanced firms. However, the second interpretation applying the bargaining power arguments seems to be even more convincing. We know that given the foreseeability problem, mixes are the best way to avoid hold-up by the VC because adequate milestones cannot be defined for the whole development process ex ante. The hold-up problem is expected to be the more pronounced, the less developed the firm at the moment of investment: the less developed the firm, the

²⁴There is an alternative interpretation for those two variables, namely that they proxy for the ex-ante distribution of bargaining power between the entrepreneur and the VC. Using this alternative interpretation does not change our results with respect to the choice of rounds vs milestone finance however.

²⁵This result is further emphasized by the dummy REFERENCE CUSTOMERS.

smaller the probability that hard facts about its success are available when new funding becomes necessary. Moreover, the same is true for the heterogeneity aspect. Thus mixes should be observed more frequently for less advanced firms and this is just what we observe in the data. Finally, VC effects and time effects can be observed.

To conclude, we find that the definition of adequate milestones for the whole development process seems to be the crucial limiting factor but we cannot completely discard the argument that the minimum duration of pure round financing may be a limiting factor as well. In addition, the influence of the hold-up potential by the VC is crucial for the choice of one specific form of staging.

Regression Results

As pointed out above, we are interested in identifying the determinants of the choice of the different forms of staging given that staging is to be implemented. The contracting parties maximize the utility they derive from a specific form of staging by taking into account the advantages and disadvantages of each form. In order to reflect this unobserved utility maximization, we use a discrete choice model. As our two interpretations of feasibility imply different logical orders for the three staging modes, we refrain from implementing such an order empirically. Therefore, the appropriate model in our situation is an unordered multinomial logit or probit model. In fact, we will run multinomial probit regressions with varying base categories to avoid the IIA assumption implicit in the multinomial logit model. The results are given in tables 13 and 14.

With respect to the decision between pure milestone financing and pure round financing, we get the following results: pure milestone financing is used significantly more often for firms which have already entered the market and which are confronted with a lower degree of asymmetric information (measured by both AI and RAI). This means that milestones as opposed to pure round financing are rather used for more advanced firms for which the project's development is predictable and thus adequate milestones can be implemented. This result clearly shows that the feasibility of milestone financing seems to be the crucial limitation when choosing between the different forms of staging. In addition, OUTSIDE FINANCE is negative and highly significant in all specifications. This indicates that milestone financing is used when the entrepreneur's outside option is relatively low as he cannot resort to former investors or additional syndicating partners when the (lead) VC denies further funding. The expected investment amount (EBS) does not turn out to be significant in our regressions anymore when explicitly controlling for the outside financing option. Thus, besides the feasibility aspect, the impact of potential hold-up by the VC is the crucial determinant. Finally, the time and VC effects which we observe in the descriptive statistics are confirmed: public VCs use significantly more pure

milestone financing, in period 1, significantly less pure milestone financing is used and in period 3 significantly more pure milestone financing is used. This indicates a steady decline in the use of pure round financing.

With respect to the use of mixes relative to pure round financing, we find that mixes are more often used for very early stage firms, i.e. for firms which are on the verge of starting their product development process. This underlines the fact that mixes are implemented to avoid hold-up when pure milestone financing is not feasible, i.e. for very early stage firms where the project's development path is unpredictable and the probability of hard facts being available when new funding becomes necessary is very low. In addition, this result may be reinforced by the contracting cost argument which states that round financing should be more probable for more advanced firms. Moreover, we again observe time and VC effects: mixes are used significantly less in period 1 and public and independent VCs are more inclined to use mixes in comparison to pure rounds. The results for independent VCs are not robust, however.

Finally, as concerns the use of mixes relative to pure milestone financing, we observe that mixes are more often used when the product development is about to start, the firm has not already entered the market, the degree of asymmetric information is relatively high and the entrepreneur's human capital is crucial. While this seems counterintuitive at first sight – we would expect that pure milestone financing should rather be used when the entrepreneur's outside financing option is worse and the heterogeneity of beliefs is pronounced, i.e. for less advanced firms – it underlines the foreseeability aspect: milestone financing is not implementable for very early stage firms. Moreover, at the same time, OUTSIDE FINANCE is negative. Although the coefficients are not significant in all our specification, the sign is always correct, indicating that milestone financing is rather used when the hold-up potential is pronounced, i.e. when the entrepreneur cannot resort to other (known) financiers. This means that both foreseeability and renegotiation aspects are important when choosing milestone financing or mixes. Finally, we find that the VC and time effects are not robust in our regressions but that there is a tendency for independent VCs to use significantly less pure milestones and that in period 3 significantly more pure milestone financing was used.

Thus we can state that the descriptive results are in line with the regressions. This means that there are two different determinants: first of all, foreseeability determines whether pure milestone financing is feasible; second, the intensity of the hold-up problem determines the choice between the available forms of staging. Contracting cost arguments do not seem to play a crucial role for the feasibility of round financing.

Summary

To sum up, the choice between the different forms of staging is driven by the anticipation of the impact of renegotiation possibilities: we find that contracts are the more complete, the more pronounced the expected negative incentive effect for the entrepreneur caused by the VC's hold-up. Thus the first part of hypothesis 2 is broadly confirmed. At the same time, the foreseeability of the project's development severely restricts contract completeness by rendering milestone financing impossible.

The highest degree of contract completeness can only be reached if foreseeability is given. This implies that pure milestone financing should be more probable for more advanced firms which is broadly confirmed by our data. If foreseeability is given, milestone financing should be used more often than mixes if the negative incentive effect is pronounced. The same should be true for the comparison between pure milestone financing and round financing. Again, this is just what we find in our data: if the entrepreneur has a good outside financing option due to contacts to former investors or other investors in the syndicate, the hold-up potential and therefore the negative incentive effects are less pronounced²⁶. Consequently, milestone financing is used less frequently than mixes and pure rounds.

If pure milestone financing cannot be implemented because foreseeability is not given, the choice to be made is only between mixes and pure round financing. In this case, mixes are the most complete contracts available. Thus mixes should be used more often than pure rounds when the impact of potential renegotiation is pronounced. Indeed, the data shows that mixes are used with less developed firms for which hard information is not expected to be available in the near future and consequently, outside funding will be difficult to obtain.

²⁶In order to test the robustness of OUTSIDE FINANCE, we ignore the existence of syndicating VCs for a moment. We conjecture, however, that the possibility of resorting to syndicating partners is crucial for the entrepreneur when the (lead) VC denies further funding. This is especially important as syndicating partners have a further informational advantage in comparison to former investors who financed the venture before the initial VC investment. It turns out that, as expected, this alternative specification hardly yields any significant results anymore. However, there is no contradiction with respect to the previously mentioned results either. For sake of brevity, we omit the relevant tables here. Of course, they are available upon request from the authors.

5 Conclusion

The aim of this paper was to analyze the determinants of staging per se as well as its different modes. Thereby, we did not only focus on the VC specific literature but also on the literature on renegotiation to deduce relevant hypotheses which we tested against our data.

We found that the decision for staging is driven by the extent of asymmetric information and uncertainty in the firm. It is important to keep in mind that we proxied for asymmetric information by taking a developmental perspective. In contrast, the tangibility of assets and the entrepreneur's human capital do not matter. With respect to these results, it is important to keep in mind the limitations of our variables. Overall, the results are quite robust and in line with earlier studies based on US data.

As regards the characteristics of milestone financing, we have presented evidence that the type of milestone used depends on the position of the firm in its development process. Very early stage firms tend to use product milestones while developed firms use financial or other milestones. Moreover, product milestones seem to be used more often with mixes between round and milestone financing. Mixes of different types of milestones, on the other hand, seem to be used more often with pure milestone financing.

Finally, we find that for the decision between the different forms of staging the investment amount does not seem to play a significant role. Rather the trade-off between the anticipation of the impact of renegotiation on the entrepreneur's incentives and the desired ex post flexibility is decisive: the more pronounced the negative incentive effect caused by renegotiation, the more complete contracts should be in order to limit hold-up by the VC. However, the degree of contract completeness is restrained by the need for predictability of the project's development path. If this requirement is not fulfilled, pure milestones (i.e. the most complete contracts) are impossible to define and mixes present a second-best choice to overcome the negative incentive effect. Both aspects are confirmed by our data. To be more precise, we show that pure milestone financing is used less frequently for very early stage firms for which predictability is less probable. Our data further confirms that the degree of contract completeness depends on the entrepreneur's outside financing option which we have measured in two forms: first, we have looked whether external funding before the investment of the VC had taken place or whether the investment has (or had) been made via a syndicate of VCs and second, we took into account whether hard information had been available.

Notes: This table shows the summary statistics of all relevant variables for the subsample of observations where specific milestones were defined. T-tests with unequal variances are made for the means between the observations where the specific milestone is used and the observations where all other milestones are used. Significance is indicated by *, **, *** for the 10%, 5% and 1% level respectively.

Table 10: The Determinants of a Specific Milestone Category (1)

Notes: Probit regression with clustered standard errors at firm-level. The dependent variable is the dummy variable OTHER MILESTONE (MILESTONE MIX) which takes value one when an other milestone (milestone mix) is used with milestone financing and 0 otherwise. Marginal effects are indicated.

Table 12: Summary Statistics for the Different Forms of Staging

| Variable | Milestones only | | | | | | Rounds only | | | | | | Mixes | | | | | |

Notes: This table shows the summary statistics of all relevant variables for the subsample of all observations where the different staging modes were used. Pairwise t-tests with unequal variances are made for the means. Significance is indicated by (*, **, ***) for the comparison between pure milestones and pure rounds; (+, ++, +++) for the comparison between pure rounds and mixes; (°, °°, °°°) for the comparison between pure milestones and mixes. They indicate the 10%, 5% and 1% significance level respectively.

Table 13: The Determinants between Pure Milestones, Pure Rounds and Mixes (1)

Notes: Multinomial probit regression with clustered standard errors at firm-level. The dependent variable is the categorical variable STAGING CATEGORIES which takes value one when pure milestone financing takes place, value 2 with mixes and value 3 when pure round financing occurs. The chosen base category is pure round finance. The comparison outcome category (OC) is indicated in the first column.

Table 14: The Determinants between Pure Milestones, Pure Rounds and Mixes (2)

| OC | Model 1 | | | Model 2 | | | Model 3 | | | Model 4 | | | Model 5 | | | Model 6 | | | Model 7 | | | Model 8 | | | |
