Capitalism, Crisis and Class: The United States Economy
After 2007-2008 Financial Crisis

Mathieu Dufour\(^1\) and Özgür Orhangazi\(^2\)

Abstract
The post-1980 era witnessed an increase in the frequency and severity of financial crises around the globe, a majority of which took place in low- and middle-income countries. Studies of the impacts of these crises have identified three broad sets of consequences. First, the burden of crises falls disproportionately on labor in general and low-income segments of society in particular. In the years following financial crises, wages and labor share of income fall, the rate of unemployment increases, the power of labor and labor unions is eroded, and income inequality and rates of poverty increase. Capital as a whole, on the other hand, usually recovers quickly and most of the time gains more ground. Second, the consequences of crises are visible not only through asset and income distribution, but also in government policies. Government policies in most cases favor capital, especially financial capital, at the expense of large masses. In addition, many crises have presented opportunities for further deregulation and liberalization, not only in financial markets but in the rest of the economy as well. Third, in the aftermath of financial crises in low- and middle-income economies, capital inflows may increase as international capital seeks to take advantage of the crisis and acquire domestic financial and nonfinancial assets. The 2007-08 financial crisis in the US provides an opportunity to extend this analysis to a leading high-income country and see if the patterns visible in other crises are also visible in this case. Using the questions and issues typically raised in examinations of low- and middle-income countries, we study the consequences of the 2007-08 US financial crisis and complement the budding literature on the “Great Recession”. In particular, we examine the impacts of the crisis on labor and capital, with a focus on distributional effects of the crisis such as changes in income shares of labor and capital and the evolution of inequality and poverty. We also analyze the role of government policies through a study of government taxation and spending policies and examine capital flows patterns.

Keywords: financial crisis, Great Recession, 2008 crisis

He is the author of Financialization and the US Economy (2008) and numerous articles and book chapters on financialization, financial crises, and alternative economic policies. He holds a Ph.D. from the University of Massachusetts Amherst (2006) and previously taught economics at Roosevelt University in Chicago (2006-2011).
1. Introduction

The post-1980 era witnessed an increase in the frequency and severity of financial crises around the globe (Eichengreen 2001; Reinhart and Rogoff 2011). Apart from the large amount of literature that examines the causes of these crises, another line of research has concerned itself with the consequences of financial crises. Three broad findings emerge from the latter, which focuses on low- and middle-income country experiences, as this is where most of the major financial crises have taken place in the last couple of decades. First, the burden of crises falls disproportionately on labor in general and low-income segments of society in particular. In the years following financial crises, wages and labor share of income fall, the rate of unemployment increases, the power of labor and labor unions is eroded, and income inequality and rates of poverty increase (Diwan 2000, 2001; Jayadev 2005; Onaran 2007). Capital as a whole, on the other hand, usually recovers quickly and most of the time gains more ground. Second, the consequences of crises are visible not only through asset and income distribution, but also in government policies. Government policies in most cases favor capital, especially financial capital, at the expense of the rest of society. In addition, many crises have presented opportunities for further deregulation and liberalization, not only in financial markets but in the rest of the economy as well (Crotty and Lee 2001; Duménil and Lévy 2006; Harvey 2003; Dufour and Orhangazi 2007, 2009). Third, in the aftermath of financial crises in low- and middle-income economies, capital inflows often increase as international capital seeks to take advantage of the crisis and acquire domestic financial and nonfinancial assets (Wade and Venoroso 1998; Dufour and Orhangazi 2007, 2009).

The 2007-08 financial crisis in the US provides an opportunity to extend this analysis to a leading high-income country and see if the patterns visible in other crises are also visible in this case. Using the questions and issues typically raised in examinations of low- and middle-income countries as an entry point to look at the experience of the US economy in the aftermath of the 2008 financial crisis provides a fresh perspective on that crisis and allows for an original contribution to the gradually emerging literature on the consequences of the financial crisis and the “Great Recession” (e.g. Wolff 2013, Oleinik 2013). In this paper, we empirically investigate the outcome using broad indicators such as changes in inequality and poverty and then compare the fortunes of labor and capital after the crisis. We find that unemployment has substantially increased and labor incomes have fallen, but the income share of capital and profitability continued to increase after the crisis. While the US did not need an external bailout, such as those the IMF provided during earlier financial crises in less-developed countries, the US government and the Federal Reserve (FED) provided unprecedented amounts of support to the economy. Since they were not constrained by an external structural adjustment program and since the FED has the power to issue an international reserve currency, the outcomes of the crisis in this regard differed from other experiences. However, capital inflows peaked during the
crisis, suggesting that it opened business opportunities for international capital in similar ways as previous crises did.

The rest of the paper is organized as follows. In the next section we look at the emergence of the crisis and the path of some important macroeconomic indicators before and after the financial crisis. In the third section we turn our attention to distributional effects of the financial crisis and then compare this with the impacts of the crisis on capital. We compare the changes in income shares of labor and capital before shifting our attention to changes in inequality and poverty. The fourth section focuses on the role of government policies through an analysis of government taxation and spending policies. After discussing the change in capital flows in the fifth section, we conclude in the last section with a discussion of our overall findings and further research areas.

2. Macroeconomics of the crisis

The last three decades have been characterized by an increase in the power of capital over labor in the US. During this period, wages declined or stagnated despite increasing productivity (Mishel 2012, Mishel and Gee 2012) and income and wealth inequality rose (Piketty and Saez 2006, Duménil and Lévy 2011). Meanwhile, the US economy became more financialized, which not only led to a further redistribution of income to finance capital, but also to an increase in financial fragility, culminating in the financial crisis of 2007-08 (Orhangazi 2008, 2011). The precise beginning of the financial crisis is difficult to determine. The number of mortgage delinquencies began rising in early 2007 and led to bankruptcies among subprime mortgage lenders. The FED, along with the world’s major central banks, perceived the problem as one of liquidity and around the summer of 2007 began injecting liquidity into world financial markets. However, in March 2008, Bear Stearns, one of the largest investment banks, almost collapsed and was acquired by JP Morgan Chase with the backing of the FED. This event made it clear that there was a major financial crisis at hand which was not limited to the subprime mortgage market. Four months later, the Federal Deposit Insurance Corporation (FDIC) had to take over IndyMac Bank. The crisis accelerated in September with the takeover of Fannie Mae and Freddie Mac, the near collapse of Merrill Lynch - acquired by Bank of America - and the bankruptcy of Lehman Brothers, along with the bailout of AIG, all happening within a month. According to the National Bureau of Economic Research (NBER), the US economy entered into a recession

---

3 There is a debate regarding the proper measures of productivity and workers’ compensation and thus of the size of the disconnection between the two (e.g. Feldstein 2008). Nonetheless, even when factors such as price deflators or inequality are set aside, a sizeable disconnection remains (Pessoa and Van Reenen 2012).
around December 2007 and the recession ended in June 2009.\textsuperscript{4} Table 1 shows some important economic indicators before, during, and after the financial crisis and the recession.

\<Table 1 approximately here>\n
The data show that this is one of the most serious downturns for the US economy historically and that the recovery has been quite limited. The annual growth performance of the economy remains well below the pre-crisis era to this day. While non-residential investment has slowly inched back up towards pre-crisis levels, residential investment is still near rock bottom at 2.6\% of GDP at the end of 2012, down from 5-6\% before the subprime trouble started. With government spending measures phasing out and further cuts imposed as a result of budget negotiations and the effective federal funds rate already as low as it can be, it is not clear whether investment will pick up in future quarters. While the share of personal consumption in the GDP remained quite high, overall its quarterly increases are still below pre-crisis levels. The trade deficit, however, shrank towards the end of the crisis and has remained lower than pre-crisis levels since then. This macro picture is not exactly rosy, but some sectors and groups in society have fared worse than others in spite, or perhaps because, of the vast government resources that were committed to the recovery. In the following sections we analyze in detail how different groups were hit by the crisis and the extent to which their fortunes have improved after the financial crisis.

3. Crisis and distribution

3.1 Unemployment and wages

To understand the consequences of a financial crisis, it is crucial to ascertain how the burden was distributed in society. Labor is a useful starting point for such an undertaking as crises typically result in increased rates of unemployment and a decrease in pay and benefits. The power of labor can also be affected in different ways if, for example, the crisis is used as a pretext for labor repression, or resistance to different measures and outcomes energizes it. Figure 1 shows two measures of the rate of unemployment – the official rate and a broader measure (labeled U – 6), which includes marginally-attached workers, such as discouraged workers and individuals working part-time for economic reasons. The rate of unemployment, which was below 5\% right before the crisis, reached almost 10\% at its peak. It has since begun to come down, but was still

\textsuperscript{4} The NBER defines a recession as “a significant decline in economic activity spread across the economy, lasting more than a few months, normally visible in real GDP, real income, employment, industrial production, and wholesale-retail sales” (http://www.nber.org/cycles.html)
recorded at 7.3% in October 2013 (Federal Reserve of St-Louis). If we include unwilling part-time workers and individuals marginally attached to the labor market, the rate started a little above 8% before the crisis and peaked at 17.1%. It has also since come down, but relatively more slowly, hovering around 14% for most of 2013 (Federal Reserve of St-Louis). This suggests that while some people are finding work, many remain underemployed or simply discouraged by their job prospects.

A look at the labor force participation rate and the proportion of the civilian population that is employed reinforces that assessment (Figure 2). The labor force participation rate, which stood above 66% before the crisis, has been dropping since 2007 and stood at 63.6% at the end of 2012 going down to 62.8% by October 2013 (Federal Reserve of St-Louis). The evolution of the rate of employment is even starker: From around 63% before the crisis, it had decreased to 58.3% by October 2013 (Federal Reserve of St-Louis), with virtually all the drop happening in 2008 and 2009. Both rates are now at their lowest since the early 1980s and show no sign of going back up. Overall, those indices offer a picture of a stagnant labor market from which many workers simply choose to exit, while many others have to make do with part-time employment.

Furthermore, there is a polarization of the workforce. Most of the employment losses since 2007 occurred in mid-wage occupations, but the jobs created afterwards have been concentrated in lower-wage occupations. Lower-wage occupations grew 2.7 times faster than mid- and high-wage jobs. According to a study by the National Employment Law Project (2012), during the recession, 21% of the job losses were in lower-wage occupations while 58% of jobs created during the recovery were low-wage jobs. 60% of the jobs lost were in mid-wage occupations and only 22% of the jobs created were mid-wage jobs. And 19% of the losses were composed of higher-wage occupations and these represented 20% of the recovery. The same report suggests that these results are due both to the fact that low-wage industries, such as food services or retail, are experiencing relatively high job growth, but also that jobs are not being created in mid-wage occupations in other industries. As a result, the proportion of workers earning wages below poverty-level increased from 23.3% in 2006 to 28% in 2011. Similarly, the proportion of men working at or below minimum wage went from 2.5% in 2006 to 4.2% in 2009, while 4.1% of women worked at or below minimum wage in 2006 compared to 6.2% in
2009 (Mishel et al. 2012: chp. 4). Table 2 shows the percentage change in real annual wages after 2007 by wage group. We observe that while the top 1% experienced a large decline in real wages immediately after the crisis, the recovery has been strong, though not enough to offset the losses. The 95-99 percentile, on the other hand, rapidly recovered its real wage losses after the crisis. However, for the bottom 90%, the change in percentage in real annual wages was negative from 2007 to 2011.

Like employment, labor income has also dropped since the beginning of the crisis. After being stagnant for over two decades, the real median hourly wage increased by a couple of 2011 dollars in the mid-1990s and stabilized at a new plateau in the early 2000s, though there was a slight decrease near the middle of the decade (Figure 3). The same pattern is apparent in median total compensation, a broader income measure that includes benefits. Strangely, both measures of income slightly increase early on in the crisis before heading down again. Upon closer examination, this seems to be the result of the slight deflation in 2009. We can suppose that wage contracts, typically negotiated in nominal terms, had a built-in inflation expectation and that one year of deflation thus boosted real incomes. In fact, if we simply impute the pre-crisis average rate of inflation\(^5\) to 2009, we get a decrease in median wage and total compensation for that year as well; there would have been a loss of about one dollar in real income (wages or total compensation). Thanks to the deflation in 2009, however, by 2011 wages were only $0.33 below their 2007 level and total compensation was virtually at the same level. Still, even that smaller decrease was enough to send the median wage back to its 1999-2000 level.

The loss of income does not seem to have been uniform across income groups. Comparing average and median total compensation (Figure 3), it can be seen that not only did the average not stagnate from the mid-1970s onward, but the drop following the crisis was relatively smaller. The drop would have been larger for average total compensation without the

---

\(^5\) We use the average inflation rate from 2000 to 2007, which was 2.73\% for the price deflator used on the income series.
deflation in 2009, but it would have set it back to 2005 levels instead of the beginning of the
decade like the median total compensation.6

Lastly, we examine whether or not there was a change in the bargaining power of labor
after the financial crisis. Unionization rates and data on work stoppages can proxy for this.
Union membership has been quite low in the US for some time. From rates around 22-24% 
during the 1970s, union membership among wage and salary workers had been experiencing a
secular decline and by the mid 2000s, it had stabilized at 12-12.5% (Figure 4). The crisis gave it a
little nudge downward and by 2012, membership was down to 11.2%. Most of the drop
happened after 2009, suggesting that union jobs were lost in the crisis and non-union jobs were
created in the recovery. The picture is even starker if we focus on the private sector. In the
1970s, 21-24% of the sector was unionized, but by 2008, union membership was a mere 7.6%.
The percentage decreased to 6.6% by 2012.

<Figure 4 approximately here>

The figures above are not surprising. In the US, workers lost a lot of power in the post-
1980 era. When we look at worker militancy proxied by work stoppages or the proportion of
work time spent idle due to work stoppages, we see that little has been happening since the early
1980s (Figure 5). In that respect, the neo-liberal era stands in stark contrast with the previous
period: There is no gradual decline akin to that of union membership, but rather a steep drop
between the 1970s and the 1980s. Union activity and work stoppages were already at a minimum
in the US before the crisis, which itself does not seem to have changed this situation. This lack
of power may explain the losses of labor.

<Figure 5 approximately here>

In short, labor in general suffered after the financial crisis both in terms of declining
employment opportunities and declining wages. The rate of unemployment reached new heights,
which is most visible in the U6 rate of unemployment. Even though it seems to have come
down from its peak, the broader measure of employment to civilian population ratio shows a
significant decline since the crisis, suggesting that most of the gains in unemployment came from
people leaving the labor force. Within labor, it appears that the bottom 90% suffered the most.

6 These statistics are for all workers. For evidence on the differential impact of the financial crisis on race and gender
see, for example, Peterson, J. 2012, Arestis et al. 2013 and Dymski et al. 2013.
The bargaining power of labor has declined as well. In terms of the power of labor, one indicator, the rate of unionization which was already at pretty low levels, further declined. Let’s now take a look at the overall distribution of income between labor and capital.

3.2. Labor vs. capital

The labor share of income, measured as total labor compensation as a percentage of GDP, illustrates the overall situation of labor after the crisis (Figure 6). This labor share of income shows a slight increase in the crisis year of 2008 and then starts falling. The same trend is observed within the corporate sector as well. Figure 7 shows the compensation of employees as a share of corporate gross value added. In the years of the financial crisis, the long-term decline in this ratio is reversed temporarily but it starts falling again to reach a new low. While labor is seeing its share of income dwindle even further as a result of the crisis, profits have fared much better. Figure 7 also depicts the share of after-tax profits within the gross value added of the corporate sector. After briefly declining in the crisis years of 2007 and 2008, this ratio reached historical heights a few years after the crisis. After experiencing a steep – but very short-lived – decline during the third quarter of 2008, in the midst of the crisis, after-tax profits as a share of GDP rose again and are now at their highest level since the Second World War.

<Figure 6 approximately here>

<Figure 7 approximately here>

The compensation of CEOs did not quite recover as quickly, though it remains at historically high levels. Two indices of the ratio of CEO-to-worker compensation developed by the Economic Policy Institute (EPI), options granted and options realized, indicate that while there was a drop in that ratio during the crisis, and especially in 2009, it remains above mid-1990s levels (Figure 8).7

<Figure 8 approximately here>

---

7 “Options realized” include salary, bonuses, restricted stock grants, long-term incentive payouts, and options exercised, while “options granted” includes the same categories, with options granted instead of realized. The measures include the CEOs of the 350 largest firms by sales. The wage measure is the hourly wage of a typical non-supervisory/production worker in the relevant industry. For a more complete discussion of the methodology used by the EPI, see Mishel and Sabadish (2002).
Figure 9 shows the after-tax profits of the nonfinancial corporate sector as a percentage of their nonfinancial assets. This ratio begins declining in 2007 as the economy slides into a recession. Soon after, though, nonfinancial corporations’ profitability not only recovers but surpasses pre-crisis levels. This is consistent with the initial drop in the profit share of corporate income (Figure 7 above).

Figure 9 approximately here>

Figure 10 shows the banking sector’s net income as a percentage of its total assets. The profitability of the banking sector took a dive with the financial crisis. As a result of the financial crisis there has been a significant redistribution and concentration of wealth and power within the financial sector. Bank of America, Citigroup, and JP Morgan Chase all increased their size and market share through acquisitions and other means. The government’s strategy of consolidating failing financial institutions resulted in the creation of mega financial institutions. In the following years there was a strong recovery in the profitability of the banking sector.

Figure 10 approximately here>

In short, labor’s share both within gross domestic product as well as within the corporate sector fell a couple of years after the crisis. If one takes the CEO-to-worker compensation ratio as another indicator, it is clear that overall capital seems to be faring better than labor in the recovery so far.

3.3 Income inequality

Income inequality in the U.S. has been increasing since the 1970s. The initial relative decrease in the CEO-to-worker compensation ratio in the midst of the crisis is illustrative of a broader temporary downward trend in income inequality. For example, the Gini coefficient, which had been increasing during the previous decades, decreased slightly in 2007 and 2008 before resuming its upward trend and reaching its highest level in 2011 (Figure 11). Similarly, the share of income going to the top quintile dropped slightly early in the crisis, but then resumed its upward movement (Figure 12). Conversely, the share of the second and third quintile rose slightly during the crisis, but then resumed the downward trend they had been experiencing in
the last three decades, while the fourth and fifth quintiles basically continued to decrease (Figure 13). Interestingly, there have been some fluctuations at the top percentiles of income distribution. While the income share of the top 1% declined during the crisis, the share of the 90th to 99th percentile actually increased during the period, mitigating the overall loss for the top 10% (Piketty and Saez 2003, updated figures). Between 2007 and 2011, the income share of the top 1%, including capital gains, decreased almost 4%, going from 23.50% to 19.82%, while the share of the top 10% only decreased about 1.5%, going from 49.74% to 48.20%. Overall, the income share decrease of the top 1% was redistributed within the top 20% and largely for the top 90-99%.

<Figure 11 approximately here>

<Figure 12 approximately here>

<Figure 13 approximately here>

Overall, inequality indices show slight improvement immediately after the crisis. This is most likely due to the decline in the market values of financial assets and the corresponding decline in their income streams. However, soon after inequality began to trend upwards again, indicating that the net effect of the financial crisis has been to increase inequality.8 On the other hand, poverty rates after the crisis have shown an unequivocal increase.

3.4 Poverty

While inequality fluctuated, poverty unequivocally increased as a result of the crisis. The rate of people living below the poverty line, as measured by the US census, increased from 12.5% in 2007 to 15% in 2011, offsetting all the progress made on that front since the 1990s (Figure 14). Data from the U. S. Census bureau also indicates that many households slid downward in terms of income. Between 2007 and 2011, the proportion of households earning less than $15,000 increased from 11.9% to 13.5% and the proportion earning between $15,000 and $24,999 went

---

8 There has also been changes in the wealth inequality (Wolff 2013, Pfeffer et al. 2013). For example, between 2007 and 2011 about one-fourth of families lost more than 75 percent of their wealth and about half lost more than 25 percent of their wealth. According to Pfeffer et al. (2013), “multivariate longitudinal analyses document that these large relative losses were disproportionately concentrated among lower-income, less educated and minority households” (p. 650).
from 11% to 11.5% (DeNavas-Walt et al. 2012). The largest decreases happened in the $75,000 - $99,999 and $100,000 - $149,999 brackets.

4. Crisis and government policies

Financial crises in low- and middle-income countries were used as opportunities to further the neoliberal agenda of deregulatory policies as well as to open up these economies to international capital. Government budgets were oriented towards generating a primary surplus in accordance with the IMF structural adjustment programs and cuts in social expenditures were common (Dufour and Orhangazi 2007, 2009). The US did not face any such external constraint. Furthermore, the FED took actions well beyond its past role and supported not only banks but also all types of other financial institutions and some nonfinancial corporations through its asset purchase programs. Immediately after the crisis, a stimulus package of $152 billion in tax rebates for 2008 was passed to be followed by a package in 2009 of $787 billion. Furthermore, around $3 trillion in government subsidies was allocated to buy toxic financial assets and recapitalize insolvent financial institutions (Tcherneva 2012: 4).

Public debt significantly increased following the crisis, showing that the government shouldered a significant part of the burden. Figure 15 presents federal government total debt as a percentage of GDP. In terms of government spending, income security spending, consisting largely of unemployment benefits, retirement benefits, disability payments, and welfare and social services payments, went up early on but has since been coming down. Nonetheless, it is still above pre-crisis levels and so are social expenditures, despite a slow decline recently (Figure 16). These trends differ from what was observed during most developing country crisis experiences. One reason behind this is that benefits such as unemployment benefits are much more established in the US and the automatic stabilizers kick in when there is a slowdown. A second reason is that the US did not have to follow an IMF structural adjustment program forcing them to cut social expenditures. Third, the US government, despite the crisis, can borrow at low interest rates, which gives it much more room than governments in developing

---

9 Moffitt (2013) finds that “aggregate per capita expenditures in safety net programs grew significantly, with particular strong growth in the SNAP, EITC, UI, and Medicaid programs” (p. 143). However, state and local governments, in many cases, had to make dramatic reductions in their spending as their tax incomes fell. For example, in the case of higher education, Barr and Turner (2013) find that despite federal aid policies becoming more generous, the decline in state budget allocations had a negative effect on colleges and universities in maintaining programming and accommodating student demand.
countries. In fact, as can be observed in Figure 17, interest payments as a percentage of current expenditures remained fairly low throughout the crisis as well as afterwards. Similarly, by looking at public debt held by foreign and international lenders, it can be seen that even during and after the crisis the US government was able to borrow from abroad because the dollar still serves as the reserve currency and there is a high level of instability in other parts of the world, especially in the Eurozone (Figure 18). Incidentally, while developing countries typically devote a great deal of resources to reserve accumulation after a crisis, a precautionary cost to ward off possible future crises (Dufour and Orhangazi 2007, 2009), the US does not have to do this so long as the dollar remains a reserve currency. This is yet another way in which the US government has greater room for maneuver than its counterparts in developing countries.10

5. Crisis and capital inflows

Some of the processes at work during and after financial crises in less-developed countries had an air of neo-colonialism (Crotty and Lee 2001, Duménil and Lévy 2006, Harvey 2003, Dufour and Orhangazi 2007, 2009). Many of the countries beset by crises were pressured to liberalize their markets or leave them open during the downturn, leading to a transfer of assets to international finance capital and other foreign capitalists who are well-positioned to acquire otherwise profitable assets negatively affected by the crisis. In this way, for example, a good share of the Turkish banking system was taken over by foreign banks following a financial crisis

10 However, this is not to say that the US government was not subject to similar pressures. Increasing budget deficits, together with the prospective long-term financial problems of Social Security and Medicare programs triggered a debate in the US on the need for fiscal austerity. In Crotty’s (2012) words “a coalition of the richest and most economically powerful segments of society, conservative politicians who represent their interests and right-wing populist groups like the Tea Party has demanded that deficits be eliminated by severe cuts at all levels of government in spending that either supports the poor and the middle class or funds crucial public investment. It also demands tax cuts for the rich and for business” (p. 79).
that occurred in 2000-2001 (Dufour and Orhangazi 2009). More generally, capital inflows increased markedly during and right after financial crises, followed by an increase in the level of profits repatriated abroad a few years down the road.

The reality faced by a country like the US is evidently different, as there are not really any international institutions or other countries able to dictate policies to its government. Nonetheless, there has been a marked increase in international capital movements during the current crisis, suggesting that some capitalists were well-positioned to seize opportunities as they presented themselves. Inward foreign direct investment (FDI) flows peaked at the beginning of the crisis and remained relatively high thereafter, while outward FDI reached new heights during the same period (Figure 19). The inward FDI is largely made up of mergers and acquisitions, with the vast majority of the capital coming from developed countries (Europe, Canada, and Japan), with a couple of notable exceptions like the purchase of 4.9% of Citigroup by the investment authority of the United Arab Emirates in 2008 (Kornecki 2013). Moreover, as inward FDI peaked in 2008, in the middle of the financial turmoil, the largest recipient of that FDI was finance, with 31.1% of the total, with depository institutions getting a further 8.1% (ibid.). This suggests that this FDI was in large part targeted at grabbing financial assets while the US financial industry was shaken and moving in to get a share of the market. Portfolio equity inflows were also high during this period, peaking in 2007 and only coming down in 2011 (Figure 20). These recent inflows have contributed to a secular rising trend in foreign ownership of equity in the US, which now stands around 10% of the total (Walker 2013).

The instability inherent in the crisis is the source of another financial transfer to countries with strong currencies: Other countries trying to ward off that instability accumulate reserves, which represents seigniorage for the countries emitting reserve currencies. While the relative importance of the US dollar as a reserve currency has declined over the last decade, over 60% of the official reserves for which the currency composition is reported (over 55% in 2012) was still denominated in US dollars in 2012 (IMF, COFER database). Between 2007 and 2012 alone, there was an increase of over 1 trillion dollars in the official reserves known to be held in dollars, going from 2,642 billion dollars to 3,764 billion dollars (ibid.).
6. Concluding remarks

The literature on the effects of the financial crises in low- and middle-income countries has three broad findings. First, the burden of the crises falls disproportionately on labor while capital as a whole quickly recovers. Unemployment increases, real wages and labor share of income declines as inequality and poverty rise. Second, government policies in the aftermath of financial crises favor capital, particularly financial capital at the expense of cuts for broader segments of the society. Third, international capital takes advantage of the financial crises by acquiring financial and nonfinancial assets at fire-sale prices. In this paper, we examined the experience of the US economy in the aftermath of the 2007-08 financial crisis in terms of the questions and issues typically raised in studies of low- and middle-income countries. We analyzed the consequences of the 2007-2008 financial crisis on different groups in the US, by looking at how the burden was shared, who suffered and by how much, and who profited. This follows a literature that developed in the wake of the increase in instability following the end of the Bretton Woods system and the advent of neoliberal economic policies. Most of this literature is concerned with financial crises in low- and middle-income countries, where instability had largely been contained prior to the 2007-2008 crisis. In this paper, we extend this literature by analyzing a crisis in a high-income country in an effort to see if the patterns present in previous financial crises in low- and middle-income countries are also visible in the US. Our findings suggest that the burden of the crisis fell disproportionately on labor and the poorer segments of society and that the power of the labor movement was further eroded, while capital recovered rapidly overall. What is more, some segments of capital were in fact able to gain from the situation. These results are in line with previous experiences. One major difference, though, is that the US government does not face the same constraints as its counterparts in low- and middle-income countries, both in terms of its ability to finance its activities and the leeway it has regarding policy-making. Consequently, financing costs did not rise dramatically even as the public debt did and public spending was relatively more stable than what was observed in previous financial crises.

These findings have strong implications for post-crisis economic policies. In the US these policies were designed to save large financial institutions and other corporations, and we observe that this was done at the expense of larger segments of the population, especially labor and the poorer segments of society. Furthermore, the findings are in general consistent with the argument that capitalism’s institutional structure and the government policies together ensure that capital in general and high-income classes in particular come out of the crisis ahead. Further research on the mechanisms of this process would be useful, to delineate more precisely how such outcomes are brought about within the system.
