Abstract

Forecast accuracy is typically measured in terms of a given loss function. However, as a consequence of the use of misspecified models in multiple model comparisons, relative forecast rankings are loss function dependent. This paper addresses this issue by using a novel criterion for forecast evaluation which is based on the entire distribution of forecast errors. We introduce the concepts of general-loss (GL) forecast superiority and convex-loss (CL) forecast superiority, and we establish a mapping between GL (CL) superiority and first (second) order stochastic dominance. This allows us to develop a forecast evaluation procedure based on an out-of-sample generalization of the tests introduced by Linton, Maasoumi and Whang (2005). The asymptotic null distributions of our test statistics are nonstandard, and resampling procedures are used to obtain the critical values. Additionally, the tests are consistent and have nontrivial local power under a sequence of local alternatives. In addition to the stationary case, we outline theory extending our tests to the case of heterogeneity induced by distributional change over time. Monte Carlo simulations suggest that the tests perform reasonably well in finite samples; and an application to exchange rate data indicates that our tests can help identify superior forecasting models, regardless of loss function.

JEL Classification: C12, C22.

Keywords: Convex loss function, Empirical processes, Forecast superiority, General loss function.

1 Introduction

Forecast comparison has a long history in econometrics. When forecast comparison is based upon the evaluation of forecast errors, loss functions are usually specified, and are defined in terms of (conditional) moments of forecast errors, such as mean squared forecast error (MSFE) and mean absolute forecast error (MAFE). Unfortunately, the forecast superiority of one model, relative to other models, is dependent on the loss function that is specified. To circumvent this issue, Granger (1999a) proposes the use of generalized loss functions $L(\cdot)$, with the following properties: (1) $L(e) = 0$, if the forecast error $e = 0$; (2) $L(e) \geq 0$ and $\text{Min}_e L(e) = 0$; and (3) $L(e)$ is monotonically non-decreasing as $e$ moves away from zero, i.e. $L(e_1) \geq L(e_2)$ if $e_1 > e_2 \geq 0$ or $e_1 < e_2 \leq 0$. We term the class of loss functions that satisfy the above three properties as general loss functions (GL or $L_G$). A second class of loss functions are defined as convex loss functions (CL or $L_C$), if in addition to satisfying the above three properties, they are convex. Indeed, convex functions include MSFE and MAFE, as well as several asymmetric functions, such as lin-lin and linex functions, see Elliott and Timmermann (2004) for details.

A natural question arising from the above discussion is the following. How do we assess different forecasts under generalized loss functions? In particular, suppose that there are $l$ sets of forecasts, with corresponding sequences of one-step-ahead (say) forecast errors, $\{e_{1t}\}, \{e_{2t}\}, \ldots, \{e_{lt}\}$, such that forecasts are to be ranked the same way, regardless of loss function. To answer this question, we introduce two concepts: general-loss (GL) forecast superiority and convex-loss (CL) forecast superiority. Simply put, a forecast error sequence GL outperforms other sequences if an economic agent with a GL loss function prefers the former to the latter. Similarly, a forecast error sequence CL outperforms other sequences if an economic agent with a CL loss function prefers the former to the latter. In the sequel, we establish a mapping between GL superiority and first order stochastic dominance, and a mapping between CL superiority and second order stochastic dominance. This allows us to develop a forecast evaluation procedure to test for GL forecast superiority and CL forecast superiority, based on an out-of-sample generalization of the tests introduced by Linton, Maasoumi and Whang (2005, hereafter LMW).

Since the influential work of Meese and Rogoff (1983, 1988), it has become common to select models using out-of-sample forecast comparison. For this reason, much attention in recent years has been given in the econometrics literature to the issue of out-of-sample predictive accuracy testing. One of the most important contributions in this area is the seminal paper of Diebold and Mariano (1995, hereafter DM), in which a test of equal predictive accuracy between two competing models is proposed. Since then, efforts have been made to generalize DM-type tests in order to account for parameter estimation error (West, 1996; West and McCracken, 1998), to allow for non-differential loss functions together with parameter estimation error (McCracken, 2000), to test for conditional predictive ability (Giacomini and White, 2006), to allow for integrated and cointegrated variables (Clements and Hendry, 1999, 2001; Corradi, Swanson and Olivetti, 2001), to address the issue of the joint comparison of more than two competing
models (Sullivan, Timmermann and White, 1999; White 2000; Hansen, 2005; Romano and Wolf, 2005; Corradi and Distasio, 2011), and to evaluate predictive intervals, conditional quantiles and predictive densities (Christoffersen, 1998; Giacomini and Komunjer, 2005; Corradi and Swanson 2005; Corradi and Swanson 2006a; Corradi and Swanson, 2006b). Other papers tackle the issue of predictive accuracy testing via the use of encompassing and related tests (Phillips, 1996; Harvey, Leybourne and Newbold, 1997; Chao, Corradi and Swanson, 2001; Clark and McCracken 2001; Corradi and Swanson, 2002; Giacomini and Komunjer, 2005). See West (2006), Clark and McCracken (2013), Corradi and Swanson (2013), and Diebold (2014) for comprehensive surveys on recent developments in forecast comparison methodology.

There are several common features of the aforementioned papers. First, most of them are based upon moments or conditional moments of the forecast errors, and researchers must specify the objective function (say, loss function or likelihood function) in order to carry out forecast evaluation. See Clements and Hendry (1993) for some limitations of this approach. Second, all of them are out-of-sample based, despite the fact that some (e.g., DM) ignore parameter estimation error. Third, most of them assume that the underlying stochastic process is stationary, which is restrictive in many empirical applications (e.g., in labor economics and macroeconomics). Indeed, we argue that it is fundamentally important to consider the possibly heterogeneous nature of economic variables and develop corresponding evaluation techniques; see Giacomini and White (2006) for details.

In this paper, our objective is to extend early work that considers moment-based tests, and to instead consider distribution-based tests. A moment-based criterion only looks in a particular direction when examining forecast errors. For example, MSFE is designed for squared error loss functions and MAFE for absolute error loss functions. GL and CL forecast superiority, however, is based on evaluation of the entire forecast error distribution, and does not require knowledge of the exact form of the loss function. When implementing our evaluation procedure, the null hypothesis is specified in terms of inequality restrictions, and this delivers a direct test of forecast superiority.

In a related recent survey paper, Corradi and Swanson (2013) discuss predictive evaluation based on distributions of losses using stochastic dominance principles. They provide motivation, a basic set-up, and test statistics, without including any formal theory or Monte Carlo results. In their paper, they take the loss function as given, and propose an evaluation criterion based on comparing cumulative loss functions $F(L(e))$, where $F(L(e))$ is the CDF of $L(e)$. They consider panels or combinations of forecasts, and ignore parameter estimation error. In contrast, we provide a forecast evaluation testing procedure which is valid under generalized loss functions, and which is based directly on the evaluation of $F(e)$, the CDF of the forecast error. Moreover, our procedure takes into account parameter estimation error and data dependence. We develop limit theory for the tests under the null and show that the tests are consistent and have nontrivial local power under a sequence of local alternatives. Additionally, the asymptotic null distributions of our test statistics are nonstandard, and resampling procedures are used
to obtain the critical values.

Other deviations from traditional moment-based forecast evaluation methods are available in the literature. For example, Granger and Pesaran (2000) argue in favor of a close link between the decision and the forecast evaluation problems. Pesaran and Skouras (2002) discuss a decision-based approach for evaluation and comparison of forecasts. Granger and Machina (2006) propose a class of realistic decision-based loss functions for forecast evaluation. Diebold and Shin (2014a,b) suggest choosing the model which has the cumulative distribution closest to a step function equal to zero over the negative real line and equal to one over positive real line. If one forecast is superior according to their criterion, named stochastic loss divergence, then it is also superior according to any piecewise linear loss function, such as $L_1$-loss or lin-lin loss. Our distribution-based forecast comparison procedure also has a link with the decision-based approach to forecast evaluation, but careful investigation of the linkages is beyond the scope of this paper.

A preponderance of tests based on (conditional) moments of forecast errors require an assumption that the underlying stochastic process is stationary. One possible explanation for this assumption is the relative ease with which asymptotic properties of corresponding test statistics can be derived. On the other hand, one popular explanation for systematic out-of-sample forecast failure in economics is the prevalence of time varying underlying data generating processes. In lieu of this fact, provide a generalization of our testing procedure to a particular type of non-stationarity (i.e., heterogeneity), which is induced by distributional change over time, see e.g. Giacomini and Rossi (2009). It should be noted that heterogeneity is plausibly of less concern in some areas of economics (say, financial economics) than in others (say, labor economics), and so we provide a procedure for heterogenous processes, and also one which assumes stationarity. In the case of stationarity, the pseudo true parameters of all competing models can be estimated consistently, and parameter estimation error is taken into account when deriving the asymptotic properties of our tests. In the case of heterogeneity, there is no need for consistent estimation of the parameters, which may change over time.

Finally, it is worth stressing that our testing procedure can be adapted to forecast combination. It has become an attractive strategy to combine competing professional forecasts or survey predictions, to aggregate crowd wisdom collected from different sources, and to combine forecasts generated by econometric models, for example. The reason for this is that combined forecasts often outperform the “best” individual forecasts, see e.g., Stock and Watson (1999), Newbold and Harvey (2002), Timmermann (2006), Elliott, Gargano, and Timmermann (2013) for detailed discussions. In standard procedures used in the literature, optimal forecast weights are generally loss function dependent, see e.g. Elliott and Timmermann, (2004). In our context, one can evaluate different forecast combinations and select combination weights based on GL and CL forecast superiority. This line of research, however, is left for future work.

The rest of the paper is organized as follows. Section 2 introduces the hypotheses and test statis-
tics under the assumption that the underlying stochastic process is stationary. In Section 3 we derive the asymptotic distribution of the test statistics, and establish the first order asymptotic validity of a bootstrap procedure used to construct critical values. Section 4 studies the power properties of the test statistics, and of their associated bootstrap analogs, under local and global alternatives. Section 5 extends our results to heterogeneous processes. We examine the finite sample performance of the tests in a series of Monte Carlo simulations, and report findings from these simulations in Section 6. An empirical illustration in which we examine exchange rate data for six industrialized countries is discussed in Section 7. Concluding remarks are gathered in Section 8. All technical details are in an appendix.

2 Hypotheses and Tests

In this section we discuss testing for GL and CL forecast superiority. The tests allow for parameter estimation error, data dependence, and comparison of multiple models, but require the underlying processes to be strictly stationary. We first make the following loss function ($L$) assumption.

Assumption A.0. $L : \mathbb{R} \to \mathbb{R}^+$ is continuously differentiable, except for finitely many points, with derivative $L'$, such that $L'(z) \leq 0$, for all $z \leq 0$, and $L'(z) \geq 0$, for all $z \geq 0$.

Definition 2.1 General-Loss (GL) outperforms $e_2$, denoted as $e_1 \succeq_G e_2$, if and only if

$$E(L(e_1)) \leq E(L(e_2))$$

for all $L \in \mathcal{L}_G$. Convex-Loss (CL) outperforms $e_2$, denoted as $e_1 \succeq_C e_2$, if and only if

$$E(L(e_1)) \leq E(L(e_2))$$

for all $L \in \mathcal{L}_C$.

We now establish a mapping between $\mathcal{L}_G$ forecast superiority and first order stochastic dominance, and between $\mathcal{L}_C$ forecast superiority and second order stochastic dominance. This mapping is instrumental for deriving direct tests for $\mathcal{L}_G/\mathcal{L}_C$ forecast superiority. Define

$$G(x) = (F_2(x) - F_1(x))\text{sgn}(x), \quad (2.1)$$

where $\text{sgn}(x) = 1$ if $x \geq 0$, and $-1$ if $x < 0$; and

$$C(x) = \int_{-\infty}^{x} (F_1(t) - F_2(t))dt1(x < 0) + \int_{x}^{\infty} (F_2(t) - F_1(t))dt1(x \geq 0), \quad (2.2)$$

where $1(\cdot)$ denotes the indicator function, which takes the value 1 if the condition is met, and 0 otherwise.

Proposition 2.2 Suppose that Assumption A.0 holds. Then $E(L(e_1)) \leq E(L(e_2))$, for all $L \in \mathcal{L}_G$, if and only if

$$G(x) \leq 0, \text{ for all } x \in \mathcal{X}. \quad (2.3)$$
Proposition 2.3 Suppose that \( \int_{-\infty}^{x} (F_1(t) - F_2(t))dt \) \((x < 0)\) and \( \int_{x}^{\infty} (F_2(t) - F_1(t))dt \) \((x \geq 0)\) are well defined for each \( x \in \mathcal{X} \). Suppose also that Assumption A.0 holds. Then \( E(L(e_1)) \leq E(L(e_2)) \), for all \( L \in \mathcal{L}_C \), if and only if
\[
C(x) \leq 0 \text{ for all } x \in \mathcal{X}.
\] (2.4)

Remarks.

First, before implementing formal tests of GL forecast superiority, we can construct a graph that contains a plot of \( G(x) \) against \( x \). When \( e_1 \succeq_C e_2 \), we expect all points to lie below or on the zero line. In other words, a crossing of the zero line in the graph indicates a violation of GL forecast superiority. Similarly, we can construct a graph that contains a plot of \( C(x) \) against \( x \). When \( e_1 \succeq_C e_2 \), we expect all points to lie below or on the zero line. In other words, a crossing of the zero line in the graph indicates a violation of CL forecast superiority.

Second, we adopt the weak concept of forecast superiority in the above propositions, in order to facilitate our specification of appropriate null hypotheses in the sequel. Namely, one forecast can outperform another forecast and at the same time be outperformed, in which case the two forecasts are equivalent in the sense that they result in the same expected loss for the loss functions in the corresponding class. Strong GL or CL forecast superiority holds by requiring that strict inequality hold in (2.3) or (2.4), for some \( x \in \mathcal{X} \).

Third, the above propositions only offer a partial ordering between forecast errors. One can generalize the concepts discussed in this paper to third or higher order stochastic dominance (as used in finance, for example). Naturally, higher order stochastic dominance relations correspond to increasingly smaller subsets of \( \mathcal{L}_C \), and careful interpretation is needed to justify such generalizations.

Fourth, we can equivalently define the above forecast superiority concepts in terms of quantiles. We do not pursue this further in this paper, for the sake of brevity. Finally, it should be noted that econometric tests for the existence of “ordered” forecast superiority involve composite hypotheses on inequality restrictions. These restrictions may be equivalently formulated in terms of distribution functions, quantiles, or moments.

2.1 Basic framework and test statistics

Suppose that there are \( l \) sets of forecast errors \( e_1, \ldots, e_l \), resulting from \( l \) forecasting models. Predictions are made for \( n \) periods, indexed from \( R \) to \( T \), so that \( n = T - R + 1 \). The predictions are made for a given forecast horizon, \( \tau \).

With a little abuse of notation, we denote \( \mathcal{X} \) to be the union of the supports of all forecast errors. Let \( \{e_{k,t+\tau} : t = 1, \ldots, T\} \) be realizations of \( e_k \), for \( k = 1, \ldots, l \). Suppose further that \( \{e_{k,t+\tau} : t = 1, \ldots, T\} \)
depends on an unknown finite dimensional parameter \( \beta_{k0} \in \Theta_k \subset \mathbb{R}^{k} \):

\[
e_{k,t+\tau} = Y_{t+\tau} - m_k(Z_{k,t+\tau}, \beta_{k0}) = Y_{t+\tau} - \tilde{m}_k(Z_{t+\tau}, \beta_0),
\]

where the random variables \( Y_t \in \mathbb{R}, Z_{k,t} \in \mathbb{R}^{p_k}, Z_t \) (is a \( \mathbb{P} \times 1 \) random vector, say) is the collection of all predictive regressors, \( \beta_0 = (\beta_{10}', \ldots, \beta_{l0}')' \) is the pseudo true parameter vector on the parameter space \( \Theta = \prod_{k=1}^{l} \Theta_k, m_k : \mathbb{R}^{p_k} \times \Theta_k \to \mathbb{R} \) and \( \tilde{m}_k : \mathbb{R}^T \times \Theta \to \mathbb{R} \). Note that \( Z_{k,t+\tau} \) is observed at time \( t \). This notation is consistent with most of the literature on forecast comparison. We allow for serial dependence of the realizations and mutual correlation across forecast errors. Let \( e_{k,t+\tau}(\beta_k) = Y_{t+\tau} - m_k(Z_{k,t+\tau}, \beta_k) = e_{k,t+\tau}(\beta_{k0}), \) and \( \hat{\beta}_{k,t} = e_{k,t+\tau}(\hat{\beta}_{k,t}) \), where \( \hat{\beta}_{k,t} \) is some possibly nonlinear estimator of \( \beta_{k0} \), whose construction and properties are detailed below.

Like West and McCracken (1998) and McCracken (2000), we allow for three different forecasting schemes which use recursive, rolling, and fixed windows of data for estimation. However, they differ in how they obtain the sequence of parameter estimates used to construct the sequence of forecasts and forecast errors. Under the recursive scheme, the sequence of forecasts is generated using updated parameter estimates. At each point in time, \( t = R, \ldots, T \), the parameter estimate, \( \hat{\beta}_{k,t} \), depends on all observables \( (Y_s, Z_{k,s}), s = 1, \ldots, t \). Under the rolling scheme, however, we use only a fixed window of the most recent \( R \) observations. That is, \( \hat{\beta}_{k,t} \) is formed using observations \( (Y_s, Z_{k,s}) \) available from \( s = t - R + 1 \) through \( t \). The fixed scheme is distinct from the previous two in that the parameters are not updated when new observations become available. The parameter vector is estimated only once, and all \( n \) forecasts and forecast errors are constructed using the same parameter estimate, i.e., \( \hat{\beta}_{k,t} = \hat{\beta}_{k,R} \).

In simple forecasting models where there is no parameter estimation error involved, results analogous to those given below can be established using substantially simpler arguments.

For \( k = 1, \ldots, l \), define

\[
F_k(x, \beta_k) = P(e_{k,t+\tau}(\beta_k) \leq x), \quad \text{and}
\]

\[
F_{k,n}(x, \hat{\beta}_{k,R:T}) = n^{-1} \sum_{t=R}^{T} 1\left(e_{k,t}(\hat{\beta}_{k,t}) \leq x\right),
\]

where \( \hat{\beta}_{k,R:T} = (\hat{\beta}_{k,R}, \ldots, \hat{\beta}_{k,T})' \). We denote \( F_k(x) = F_k(x, \beta_{k0}) \). Now define the following functionals of the joint distribution \( F(x_1, \ldots, x_l) \) of \( (e_1, \ldots, e_l) \)

\[
TG^+ = \max_{k=2, \ldots, l} \sup_{x \in X^+} G_k(x), \quad TG^- = \max_{k=2, \ldots, l} \sup_{x \in X^-} G_k(x)
\]

\[
TC^+ = \max_{k=2, \ldots, l} \sup_{x \in X^+} C_k(x), \quad TC^- = \max_{k=2, \ldots, l} \sup_{x \in X^-} C_k(x)
\]

where

\[
G_k(x) = (F_k(x) - F_k(x)) sgn(x),
\]

(2.7)
and
\[ C_k(x) = \int_{-\infty}^{x} (F_1(s) - F_k(s))ds1(x < 0) + \int_{x}^{\infty} (F_k(s) - F_1(s))ds1(x \geq 0). \]  (2.8)

In the sequel, without loss of generality, we assume that the union of the supports, \( \mathcal{X} \), is bounded,\(^1\) as do Klecan, McFadden, and McFadden (1991) and LMW. Notice that given the nature of our test, one only needs to verify stochastic equicontinuity for \( x \in \mathcal{X}^+ \) and \( x \in \mathcal{X}^- \) separately, where \( \mathcal{X}^+ = \mathcal{X} \cap \mathbb{R}^+ \) and \( \mathcal{X}^- = \mathcal{X} \cap \mathbb{R}^- \) with \( \mathbb{R}^+ \equiv \{x \in \mathbb{R}, x \geq 0\} \) and \( \mathbb{R}^- = \mathbb{R} \\setminus \mathbb{R}^+ \). The hypotheses of interest can now be stated as

\[ H_0^{TG} : TG^+ \leq 0 \cap TG^- \leq 0 \text{ vs. } H_1^{TG} : TG^+ > 0 \cup TG^- > 0 \]  (2.9)

and

\[ H_0^{TC} : TC^+ \leq 0 \cap TG^- \leq 0 \text{ vs. } H_1^{TC} : TC^+ > 0 \cup TC^- > 0. \]  (2.10)

In formulating the null hypothesis, \( H_0^{TG} \), we take \( \epsilon_1 \) as the benchmark forecast error, i.e. we take the corresponding model (model 1, say) as the benchmark model. Failure to reject the null implies that \( \epsilon_1 \) GL outperforms \( \epsilon_k \) for \( k = 2, \ldots, l \). On the other hand, rejection means that \( \epsilon_1 \) does not GL outperform \( \epsilon_k \), for \( k = 2, \ldots, l \). If we do not reject \( H_0^{TG} \), we can discard all of the \( k = 2, \ldots, l \) competitors, as they are all GL dominated. Likewise for the CL forecast superiority test.

The test statistics that we consider are based on scaled empirical analogues of (2.5) and (2.6). They are defined to be

\[ TG_n^+ = \max_{k=2, \ldots, l} \sup_{x \in \mathcal{X}^+} \sqrt{n}G_{k,n}(x) \text{ and } TG_n^- = \max_{k=2, \ldots, l} \sup_{x \in \mathcal{X}^-} \sqrt{n}G_{k,n}(x) \]

and

\[ TC_n^+ = \max_{k=2, \ldots, l} \sup_{x \in \mathcal{X}^+} \sqrt{n}C_{k,n}(x) \text{ and } TC_n^- = \max_{k=2, \ldots, l} \sup_{x \in \mathcal{X}^-} \sqrt{n}C_{k,n}(x), \]

where

\[ G_{k,n}(x) = \left( F_{k,n}(x, \hat{\beta}_{1,R:T}) - F_{1,n}(x, \hat{\beta}_{1,R:T}) \right) \text{ and } C_{k,n}(x) = \left\{ \int_{-\infty}^{x} \left( F_{1,n}(s, \hat{\beta}_{1,R:T}) - F_{k,n}(s, \hat{\beta}_{k,R:T}) \right)ds1(x < 0) + \int_{x}^{\infty} \left( F_{k,n}(s, \hat{\beta}_{k,R:T}) - F_{1,n}(s, \hat{\beta}_{1,R:T}) \right)ds1(x \geq 0) \right\}. \]

We next discuss how to compute the suprema in \( TG_n^+ (TG_n^-) \) and \( TC_n^+ (TC_n^-) \) and the integrals in \( TC_n^+ (TC_n^-) \). There have been a number of suggestions in the literature that exploit the step-function nature of \( F_{k,n} (\cdot, \hat{\beta}_{k,R:T}) \). The supremum in \( TG_n^+ (TG_n^-) \) can be exactly replaced by a maximum taken over all the distinct points in the combined sample. Different methods can be applied in simulations and empirical applications to ensure good finite sample performance of the test. Regarding the computation of \( TC_n^+ (TC_n^-) \), using integration by parts, we can compute \( C_{k,n}(x) \) with

\[ \hat{C}_{k,n}(x) = \frac{1}{n} \sum_{t=R}^{T} \left\{ \left[ (\epsilon_{1,t+t} - x) \text{sgn}(x) \right]_+ - \left[ (\epsilon_{k,t+t} - x) \text{sgn}(x) \right]_+ \right\}, \]

\(^1\) Technically speaking, this will facilitate the establishment of stochastic equicontinuity for the underlying empirical processes our theory is based upon.
provided that $E|e_{k,l}| < \infty$. Where $[x]_+ = \max\{0, x\}$.

To reduce computation time, it may be preferable to compute approximations to the suprema in $TG_n^+$ ($TG_n^-$) and $TC_n^+$ ($TC_n^-$) by taking maxima over some smaller grid of points $\mathcal{X}_N = \{x_1, ..., x_N\}$, where $N < n$. Theoretically, the distribution theory is unaffected by using this approximation as the set of evaluation points becomes dense in the joint support.

Note that in principle, one can also formulate $H_0^{TG}$ as $TG \leq 0$ versus $TG > 0$, where

$$TG = \max_{k=2,...,l} \sup_{x \in \mathcal{X}} (F_k(x) - F_1(x)) \text{sgn}(x),$$

and one can proceed by constructing the following statistic:

$$TG_n = \max_{k=2,...,l} \sup_{x \in \mathcal{X}} \sqrt{n}G_{k,n}(x) = \max_{k=2,...,l} \sup_{x \in \mathcal{X}} \sqrt{n} \left( F_{k,n} \left(x, \hat{\beta}_{k,R:T}\right) - F_{1,n} \left(x, \hat{\beta}_{1,R:T}\right) \right) \text{sgn}(x).$$

The problem here is that there is a failure of stochastic equicontinuity around $x = 0$. Whether we can address this by replacing the sign function with a smooth function is left to future research. In the sequel, we rely on the formulation in (2.9)-(2.10).

### 3 Asymptotic Null Distributions

The hypotheses in (2.9) and (2.10) are composite hypotheses, since $H_0^{TG} = H_0^{TG+} \cap H_0^{TG-}$, where $H_0^{TG+} : TG^+ \leq 0$, $H_0^{TG-} : TG^- \leq 0$, and since $H_0^{TC} = H_0^{TQC+} \cap H_0^{TQC-}$, where $H_0^{TQC+} : TC^+ \leq 0$, $H_0^{TQC-} : TC^- \leq 0$. Hence, in order to test $H_0^{TG}$, we separately test $H_0^{TG+}$ vs. $H_1^{TG+}$, and $H_0^{TG-}$ vs. $H_1^{TG-}$. Then, we (do not) reject the null at a level not higher than $\alpha$, using Holm bounds (Holm, 1979).

Before establishing the asymptotic distributions of our test statistics, we require a few assumptions.

#### 3.1 Assumptions and asymptotic null distributions

Let $\|\cdot\|$ denote the Euclidean norm and let $\|X\|_q$ denote the $L_q$ norm, with $(E|X|^q)^{1/q}$, for a random variable $X$. Let $\sup_t$ denote $\sup_{R \leq t \leq T}$ and $\sum_t$ denote $\sum_{t=R}^T$. We require the following assumptions in order to analyze the asymptotic behavior of our test statistics.

**Assumption A.1.** (i) $\{Y_t, Z_{k,t}\} : t \geq 1$ is a strictly stationary and $\alpha$–mixing sequence with mixing coefficients $\alpha(l) = O(l^{-C_0})$, for some $C_0 > \max\{(q-1)(q+1), 1 + 2/\delta\}$, with $k = 1, ..., l$, where $q$ is an even integer that satisfies $q > 3(L_{\max} + 1)/2$. Here, $L_{\max} = \max\{L_1, ..., L_l\}$ and $\delta$ is a positive constant.

(ii) For $k = 1, ..., l$, $m_k(Z_{k,t}, \beta_k)$ is differentiable a.s. with respect to $\beta_k$, in the neighborhood $\Theta_{k0}$ of $\beta_{k0}$, with $M_k(Z_{k,t}, \beta) = (\partial/\partial \beta)m_k(Z_{k,t}, \beta)$ satisfying $\sup_{\beta \in \Theta_{k0}} \|M_k(Z_{k,t}, \beta)\|_2 < \infty$.

(iii) The conditional distribution, $F_k(\cdot|Z_{k,t})$, of $e_{k,t}$ given $Z_{k,t}$ has bounded density with respect to the Lebesgue measure a.s. and $\|e_{k,t}\|_{2+\delta} < \infty$, for $k = 1, ..., l$.

**Assumption A.2.** For $k = 1, ..., l$, and $t = R, ..., T$, the estimate $\hat{\beta}_{k,t}$ satisfies $\hat{\beta}_{k,t} - \beta_{k0} = B_k(t)H_k(t)$, where $B_k(t)$ is a $P_k \times L_k$ matrix and $H_k(t)$ is $L_k \times 1$, with:

(i) $B_k(t) \rightarrow B_k$ a.s., where $B_k$ is a matrix of rank $P_k$;
(ii) \( H_k(t) = t^{-1} \sum_{s=1}^{t} h_{k,s}, R^{-1} \sum_{s=-R+1}^{t} h_{k,s} \) and \( R^{-1} \sum_{s=1}^{R} h_{k,s} \) for the recursive, rolling and fixed schemes, respectively, where \( h_{k,s} \equiv h_{k,s}(\beta_{k0}); \)

(iii) \( E(h_{k,s}(\beta_{k0})) = 0; \) and

(iv) \( ||h_{k,s}(\beta_{k0})||_{2,\delta} < \infty \) for some \( \delta > 0. \)

**Assumption A.3.** (i) The function \( F_k(x, \beta_k) \) is differentiable with respect to \( \beta_k \) in a neighborhood \( \Theta_{k0} \) of \( \beta_{k0}, \) for \( k = 1, \ldots, l. \)

(ii) For \( k = 1, \ldots, l, \) and for all sequence of positive constants \( \{\xi_n : n \geq 1\}, \) such that \( \xi_n \to 0, \)
\[ \sup_{x \in \mathcal{X}} \sup_{\beta : ||\beta - \beta_{k0}|| < \xi_n} \left| \left( \frac{\partial F_k(x, \beta)}{\partial \beta} \text{sgn}(x) - \Delta_{k0}(x) \right) \right| = O(\xi_n^q), \]

where \( \Delta_{k0}(x) = \partial F_k(x, \beta_{k0})/\partial \beta \text{sgn}(x). \)

(iii) \( \sup_{x \in \mathcal{X}} ||\Delta_{k0}(x)|| < \infty \) for \( k = 1, \ldots, l. \)

**Assumption A.4.** \( R, n \to \infty, \) as \( T \to \infty; \) and \( \lim_{T \to \infty}(n/R) = \pi, \) such that \( \pi \in [0, \infty). \)

For testing \( H_0^{TC}, \) we need the following modifications of Assumptions A.1 and A.3.

**Assumption A.1.** (i) \( \{Y_t, Z_{k,t}': t \geq 1\} \) is a strictly stationary and \( \alpha-\)mixing sequence with mixing coefficients \( \alpha(l) = O(l^{-C_0}), \) \( C_0 > \max\{r q/(r-q), 1+2/\delta\}, \) with \( k = 1, \ldots, l \) and \( r > q > \max+1, \)

where \( \delta \) is a positive constant.

(ii) For \( k = 1, \ldots, l, \) \( m_k(Z_{k,t}, \beta_k) \) is differentiable a.s. with respect to \( \beta_k \) in the neighborhood \( \Theta_{k0} \)

\( \text{of} \ \beta_{k0}, \) with \( M_k(Z_{k,t}, \beta) \equiv (\partial/\partial \beta)m_k(Z_{k,t}, \beta) \) satisfying \( \sup_{\beta \in \Theta_{k0}} ||M_k(Z_{k,t}, \beta)||_r < \infty. \)

(iii) \( ||e_k||_r < \infty, \) for \( k = 1, \ldots, l. \)

**Assumption A.3.** (i) Assumption A.3(i) holds.

(ii) For \( k = 1, \ldots, l, \) and for all sequence of positive constants \( \{\xi_n : n \geq 1\}, \) such that \( \xi_n \to 0, \)
\[ \sup_{x \in \mathcal{X}} \sup_{\beta : ||\beta - \beta_{k0}|| < \xi_n} \left| \left( \frac{\partial}{\partial \beta} \text{sgn}(x) - \Delta_{k0}(x) \right) \right| = O(\xi_n^q), \]

where \( \Delta_{k0}(x) = (\partial/\partial \beta)\left\{ \int_x^\infty F_k(t, \beta_{k0}) dt (x < 0) + \int_x^\infty (1 - F_k(t, \beta)) dt (x \geq 0) - \Lambda_{k0}(x) \right\} = O(\xi_n^q), \)
\( \text{for} \ \sup_{x \in \mathcal{X}} ||\Lambda_{k0}(x)|| < \infty, \) for \( k = 1, \ldots, l. \)

**Remarks.** The first and third assumptions parallel those imposed by LMW. The only difference is that we strengthen the uniform continuity conditions in Assumptions A.3 and A.3*. Alternatively, one can assume that the marginal distributions are second order continuously differentiable. Assumption A.1 is needed in order to verify the stochastic equicontinuity of the empirical process for a class of bounded functions that appear in the \( T G_n \) test. Assumption A.1* introduces a trade-off between mixing sizes and moment conditions and is used to verify the stochastic equicontinuity result for the possibly unbounded functions that appear in the \( T \) \( C_n \) test. Assumptions A.3 and A.3* differ in the amount of smoothness required. For the CL forecast superiority test, less smoothness is required.

Assumption A.2 is identical to Assumption 1 in McCracken (2000). Notice that we have suppressed the dependence of \( B_k(t) \) and \( H_k(t) \) on the window size, \( R. \) See West (1996) and McCracken (2000) for discussions about this assumption. Assumption A.4 is identical to Assumption 2 of McCracken (2000).
When there is no parameter estimation error, we can dispense with the moment conditions for $TG_n$, and only need a first moment condition for $TC_n$. The smoothness conditions on $F_k$, $k = 1, \ldots, l$, and Assumption A.2 are also redundant in this case.

To derive the asymptotic null distributions of our test statistics, we define the empirical processes in $(x, \beta)$

$$v_{k,n}^q(x, \beta) = \frac{1}{\sqrt{n}} \sum_{t=R}^{T} \{1(e_{k,t+r}(\beta) \leq x) - F_k(x, \beta)\} sgn(x) \quad \text{and}$$

$$v_{k,n}^c(x, \beta) = \frac{1}{\sqrt{n}} \sum_{t=R}^{T} \left\{ \int_{-\infty}^{x} [1(e_{k,t+r}(\beta) \leq s) - F_k(s, \beta)] ds 1(x < 0) - \int_{x}^{\infty} [1(e_{k,t+r}(\beta) \leq s) - F_k(s, \beta)] ds 1(x \geq 0) \right\}.$$

Let $(\bar{g}_k(\cdot), v_{k0}, v_{10})'$ be a mean zero Gaussian process with covariance function given by

$$\Omega_{k}^{q}(x_1, x_2) = \lim_{T \to \infty} E \left( \begin{array}{c} v_{k,n}^q(x_1, \beta_{k0}) - v_{1,n}^q(x_1, \beta_{10}) \\ \sqrt{nH_{k,n}} \\ \sqrt{nH_{1,n}} \end{array} \right) \left( \begin{array}{c} v_{k,n}^q(x_2, \beta_{k0}) - v_{1,n}^q(x_2, \beta_{10}) \\ \sqrt{nH_{k,n}} \\ \sqrt{nH_{1,n}} \end{array} \right)'$$

where $H_{k,n} = n^{-1} \sum_{t=R}^{T} H_k(t)$. We analogously define $(\bar{c}_k(\cdot), v_{k0}, v_{10}'$ to be a mean zero Gaussian process with covariance function given by

$$\Omega_{k}^{c}(x_1, x_2) = \lim_{T \to \infty} E \left( \begin{array}{c} v_{k,n}^c(x_1, \beta_{k0}) - v_{1,n}^c(x_1, \beta_{10}) \\ \sqrt{nH_{k,n}} \\ \sqrt{nH_{1,n}} \end{array} \right) \left( \begin{array}{c} v_{k,n}^c(x_2, \beta_{k0}) - v_{1,n}^c(x_2, \beta_{10}) \\ \sqrt{nH_{k,n}} \\ \sqrt{nH_{1,n}} \end{array} \right)'$$

It is worth mentioning that the limiting distributions for $\sqrt{nH_{k,n}}$, $k = 1, \ldots, l$, can be different depending on the forecasting schemes and the parameter $\pi$. If we define $\Gamma_k(j) = E \left( h_{k,th_{k,t-j}} \right)$, we can verify that the limiting variance of $\sqrt{nH_{k,n}}$ is given by $\Omega_k = \gamma \sum_{j=-\infty}^{\infty} \Gamma_k(j)$ where

<table>

Obviously, $\gamma = 0$ when $\pi = 0$, indicating the case when parameter estimation error vanishes asymptotically.

The limiting null distributions of our test statistics are given in the following theorem.
Theorem 3.1 (a) Suppose that Assumptions A.1-A.4 hold. Then, under $H_0^{TG^+}$,

$$TG^+_n \Rightarrow \max_{k=2,...,l} \sup_{x \in B^+_k} [\tilde{g}_k(x) + \Delta_{k0}(x)'B_kv_{k0} - \Delta_{10}(x)'B_1v_{10}], \text{ if } TG^+ = 0$$

$$\Rightarrow -\infty \quad \text{if } TG^+ < 0,$$

and under $H_0^{TG^-}$,

$$TG^-_n \Rightarrow \max_{k=2,...,l} \sup_{x \in B^-_k} [\tilde{g}_k(x) + \Delta_{k0}(x)'B_kv_{k0} - \Delta_{10}(x)'B_1v_{10}], \text{ if } TG^- = 0$$

$$\Rightarrow -\infty \quad \text{if } TG^- < 0,$$

where $B^+_k = \{ x \in \mathcal{X}^+ : F_1(x) = F_k(x) \}$ and $B^-_k = \{ x \in \mathcal{X}^- : F_1(x) = F_k(x) \}.$

(b) Suppose that Assumptions A.1*, A.2, A.3* and A.4 hold. Then, under $H_0^{TC^+}$,

$$TC^+_n \Rightarrow \max_{k=2,...,l} \sup_{x \in B^+_k} [\tilde{g}_k(x) + \Lambda_{k0}(x)'B_kv_{k0} - \Lambda_{10}(x)'B_1v_{10}], \text{ if } TC^+ = 0$$

$$\Rightarrow -\infty \quad \text{if } TC^+ < 0,$$

and under $H_0^{TC^-}$,

$$TC^-_n \Rightarrow \max_{k=2,...,l} \sup_{x \in B^-_k} [\tilde{g}_k(x) + \Lambda_{k0}(x)'B_kv_{k0} - \Lambda_{10}(x)'B_1v_{10}], \text{ if } TC^- = 0$$

$$\Rightarrow -\infty \quad \text{if } TC^- < 0,$$

where $B^+_k = \{ x \in \mathcal{X}^+ : \int_x^\infty (F_1(s) - F_k(s))ds1(x \geq 0) = 0 \}$ and $B^-_k = \{ x \in \mathcal{X}^- : \int_x^- (F_k(s) - F_1(s))ds1(x \leq 0) = 0 \}.$

The asymptotic null distributions of $TG^+_n$ ($TG^-_n$) and $TC^+_n$ ($TC^-_n$) depend on the pseudo true parameters $\{\beta_{k0} : k = 1,...,l\}$ and the distribution functions $\{F_k(\cdot) : k = 1,...,l\}$. This implies that the asymptotic critical values for $TG^+_n$ ($TG^-_n$) and $TC^+_n$ ($TC^-_n$) cannot be tabulated.

3.2 Critical values based on stationary bootstrap

The stationary bootstrap is used to approximate the asymptotic null distributions of our test statistics. In our context, the null essentially consists of an infinite number of composite hypotheses involving inequality restrictions. This negates the use of standard methods for imposing the null in bootstrapping. In addition, the mutual dependence of the forecast errors and the time series dependence in the data also complicates the issue considerably. However, it turns out that the stationary bootstrap can be applied to $TG^+_n$ and $TG^-_n$, in the sense that first order asymptotic validity of appropriate bootstrap statistics can be established. Arguments using the stationary bootstrap with $TC^+_n$ and $TC^-_n$ are similar and hence are omitted.
More specifically, our objective is to find a bootstrap procedure that mimics the asymptotic null distribution in the least favorable case, where $F_1(x) = \ldots = F_l(x)$, for all $x \in \mathcal{X}^+$. We use stationary bootstrap since it ensures that the resampled series are also stationary and mixing, conditional on the original data. See Politis and Romano (1994a, b) for complete details.

For a suitably chosen random index $\theta(t)$, the resampled statistic is computed as

$$TG_n^{*+} = \max_{k=2,\ldots,l} \sup_{x \in \mathcal{X}^+} \sqrt{n} \left( G_{k,n}^*(x) - G_{k,n}(x) \right)$$

where

$$G_{k,n}(x) = \left( \overline{F}_{k,n} \left( x, \hat{\beta}_{k,\theta(R);\theta(T)} \right) - \overline{F}_{1,n} \left( x, \hat{\beta}_{1,\theta(R);\theta(T)} \right) \right) sgn(x)$$

and

$$\overline{F}_{k,n} \left( x, \hat{\beta}_{k,\theta(R);\theta(T)} \right) = n^{-1} \sum_{t=1}^{T} 1 \left( e_{k,\theta(t)+\tau} \left( \hat{\beta}_{k,\theta(t)} \right) \leq x \right)$$

In the sequel, we require a smoothing parameter $S_n$, which satisfies Assumption A.5 below.

**Assumption A.5.** The smoothing parameter, $S_n$, satisfies: $0 < S_n < 1$, $S_n \to 0$, and $nS_n^2 \to \infty$, as $n \to \infty$.

To implement the stationary bootstrap, follow the algorithm proposed in Politis and Romano (1994b).

1. Select $S_n$.
2. Set $t = R$. Draw $\theta(R)$ at random, uniformly and independently from $\{R, \ldots, T\}$.
3. Increment $t$. If $t \leq T$, draw a random variable $V \sim$ Uniform $(0, 1)$, independent of all other random variables. Stop if $t > T$. (a) If $V < S_n$, draw $\theta(t)$ at random, independently and uniformly from $\{R, \ldots, T\}$; (b) If $V \geq S_n$, set $\theta(t) = \theta(t-1) + 1$; if $\theta(t) > T$, reset $\theta(t) = R$.
4. Repeat (3).

The procedure delivers geometrically distributed blocks of random length, with mean block length $1/S_n$, as discussed in Politis and Romano (1994a).

When there is no parameter estimation error, so that $\hat{\beta}_{k_0}, k = 1, \ldots, l$, is used instead of $\hat{\beta}_{k,\theta(R);\theta(T)}$ in the definition of $G_{k,n}^*$, Theorem 3.1 in Politis and Romano (1994b) applies immediately. Let $U_i = (Y_t, Z^i_{1,t}, \ldots, Z^i_{\tau,t})'$, for $t = 1, \ldots, T+\tau$. Under some regularity conditions, the distribution of $\sqrt{n} \left( G_{k,n}^* - G_{k,n} \right)$, conditional on $\{U_{R+\tau}, \ldots, U_{T+\tau}\}$, converges to that of $\sqrt{n} (G_k - G_k)$. Then by the continuous mapping theorem, we can approximate the asymptotic distribution of $\sqrt{n} G_{k,n}$ for the elements of the null least favorable to the alternative, i.e. $G_k = 0$, for all $k$. When $\hat{\beta}_{k,\theta(R);\theta(T)}$ appears in $G_{k,n}^*$, we find that $\hat{\beta}_{k,T}$ obeys the law of the iterated logarithm. The following then holds (see, e.g., White (2000)).

**Assumption A.6.** For an arbitrary $P_k \times 1$ vector $\lambda_k$ with $\lambda_k \lambda_k = 1$, and for $k = 1, \ldots, l$, using the notation in Assumption 2, we have

$$(i) \quad P \left[ \limsup_{t \geq R} n^{1/2} \left| \lambda_k' \hat{\beta}_{k,t} - \hat{\beta}_{k0} \right| \right] / \{\lambda_k' \Sigma_k \lambda_k \log \log (\lambda_k' \Sigma_k \lambda_k) P\}^{1/2} = 1$$

for the recursive scheme, where $\Sigma_k = B_k [\lim_{T \to \infty} \var(n^{-1/2} \sum_{t=R+1}^T H_k(t))] B_k'$.

---

Note that in our setup, if the number of competing models, $l$, is small relative to the number of forecasts, $n$, size distortion is not significant (Hansen, 2003).
Theorem 3.2 Suppose that Assumptions A.1-A.3 and A.5-A.6 hold and that \((n/R)\log \log R \to 0\), as \(T \to \infty\). Then, for \(x \in X^+\) or \(x \in X^-\),

\[
\rho(L[\max_{k=2,\ldots} \sup_{x \in X^+} \sqrt{n}(G_{k,n}^+(x) - G_{k,n}(x))|U_1,\ldots,U_{T+\tau}], L[\max_{k=2,\ldots} \sup_{x \in X^+} \sqrt{n}(G_{k,n}^+(x) - G_{k,n}(x))]) \to 0,
\]

as \(T \to \infty\), where \(k=2,\ldots, l\), \(\rho\) is any metric metrizing weak convergence, and \(L[\cdot]\) denotes the probability law of the corresponding Hilbert space valued random variable.

The condition \((n/R)\log \log R \to 0\) appearing in the above theorem is slightly stronger than \(n/R \to 0\), which is required in West (1996). However, the stationary bootstrap procedure does not require recomputing the estimates \(\hat{\beta}_{k,t}\). Note that, while estimation error is allowed for, we require that it vanishes as the sample gets large. An immediate implication of the above result is the following corollary.

Corollary 3.3 Suppose that Assumptions A.1-A.3 and A.5-A.6 hold, and that \((n/R)\log \log R \to 0\), as \(T \to \infty\). Then, as \(T \to \infty\),

\[
\rho(L[\max_{k=2,\ldots} \sup_{x \in X^+} \sqrt{n}(G_{k,n}^+(x) - G_{k,n}(x))|U_1,\ldots,U_{T+\tau}], L[\max_{k=2,\ldots} \sup_{x \in X^+} \sqrt{n}(G_{k,n}^+(x) - G_{k,n}(x))]) \to 0,
\]

The asymptotic null distribution of \(TG_n^+\) (\(TG_n^-\)) can be approximated using \(TG_n^{\pm} - TG_n^+\) (\(TG_n^{\pm} - TG_n^-\)), for the elements of the null least favorable to the alternative. To do so, specify the number of bootstrap resamples, \(B\), and the smoothing parameter, \(S_n\). Choose \(B\) to be a moderately large number, say 200 or 300, as \(B\) determines the accuracy of the \(p\)-values estimated. \(S_n\) is closely connected with data dependence. The more data dependence, the smaller \(S_n\) should be. One might select \(S_n\) to be data driven, following Hall, Horowitz, and Jing (1995), for example. In the following simulations and applications, we choose a set of \(S_n\) that satisfies Assumption A.5.

Once \(B\) and \(S_n\) are determined, bootstrap critical values can be estimated straightforwardly. Define \(q_{n,S_n}^{G_+}(1-\alpha)\) to be the \((1-\alpha)\)-th sample quantile of \(TG_n^+ = \max_{k=2,\ldots} \sup_{x \in X^+} \sqrt{n}(G_{k,n}^+(x) - G_{k,n}(x))\) and \(q_{n,S_n}^{G_-}(1-\alpha)\) to be the \((1-\alpha)\)-th sample quantile of \(TG_n^- = \max_{k=2,\ldots} \sup_{x \in X^-} \sqrt{n}(G_{k,n}^+(x) - G_{k,n}(x))\). Alternatively, estimate bootstrap \(p\)-values, \(p_{B,n,S_n}^{G_+} = \frac{1}{B} \sum_{i=1}^{B} 1(TG_n^{G_+} \geq TG_n^+_i)\). Bootstrap \(p\)-values of \(TG_n^-, TG_n^{G_+}\), and \(TG_n^{G_-}\) can be defined analogously. Then, use the following rules (Holm, 1979):

**Rule TG:** Reject \(H_0^{TG}\) at level \(\alpha\), if \(\min \left\{ p_{B,n,S_n}^{G_+}, p_{B,n,S_n}^{G_-} \right\} \leq \alpha/2\).

**Rule TC:** Reject \(H_0^{TC}\) at level \(\alpha\), if \(\min \left\{ p_{B,n,S_n}^{G_+}, p_{B,n,S_n}^{G_-} \right\} \leq \alpha/2\).
It is clear that Holm bounds are equivalent to Bonferroni bounds when there are only two hypotheses. Our tests do not satisfy the requirement of asymptotic similarity and thus they are asymptotically biased, like many other tests for multiple inequality restrictions. Hansen (2003) shows that $p$-values associated with use of the stationary bootstrap test are actually upper bounds for an asymptotically unbiased test. In our context, one can follow Hansen (2003) in order to propose an asymptotically unbiased test, but this is beyond the scope of the current paper. Moreover, simulation results show that use of the stationary bootstrap yields tests with good finite sample properties. This finding is consistent with the fact that asymptotically unbiased tests do not necessarily dominate tests carried out using the stationary bootstrap tests in finite samples. In a follow up to this paper, Corradi, Jin and Swanson (2015), building on the work of Linton, Song and Whang (2010), introduce bootstrap tests for GL and CL superiority that are uniformly asymptotically valid under the null hypothesis and have exact asymptotic size over the boundary of the null hypotheses. These tests also allow for the specification of semiparametric models, and allow for non vanishing recursive and/or rolling estimation error.

4  Asymptotic Power Properties

Global and local power properties of GL forecast superiority tests are investigated in this section. Analogous results can be established for CL forecast superiority tests, using arguments similar to those presented below.

We first show that the $TG^+_n$ ($TG^-_n$) test is consistent against the fixed alternative hypothesis, $H_1^{TG^+}$ ($H_1^{TG^-}$).

**Theorem 4.1** Suppose that Assumptions A.1-A.4 hold. Then, under $H_1^{TG^+}$,

\[
P(TG^+_n > q_{n,S_n}^{G^+}(1-\alpha)) \to 1 \text{ as } T \to \infty,
\]

and under $H_1^{TG^-}$,

\[
P(TG^-_n > q_{n,S_n}^{G^-}(1-\alpha)) \to 1 \text{ as } T \to \infty.
\]

Next, consider the power of the $TG^+_n$ ($TG^-_n$) test against a sequence of contiguous local alternatives converging to the null at rate $n^{-1/2}$. Denote $F_{k,n}(\cdot, \beta_k)$ as the distribution function of $e_{k,t}(\beta_k) \equiv e_{n,k,t}(\beta_k)$, and let $F_{k,n}(\cdot) = F_{k,n}(\cdot, \beta_{k0})$. Consider the following sequence of local alternative distribution functions:

\[
F_{k,n}(x) = F_k(x) + n^{-1/2} \delta_k(x), \text{ for } k = 1, \ldots, l \text{ and } n = 1, 2, \ldots,
\]

3Simulations show that asymptotically unbiased tests are less conservative in experiments where there is "movement" away from the least favorable case, although use of the stationary bootstrap delivers tests that perform better in terms of power, in some of the cases examined. We also tried subsampling, as an alternative approach to critical value construction; but simulation results were less satisfactory in all experiments, and so these results are not reported.
where $\delta_k(\cdot)$ are real functions such that $F_{k,n}(\cdot)$ are distribution functions for each $k$ and for each $n$; and where the distribution functions $\{F_k(\cdot) : k = 1, \ldots, l\}$ satisfy $H_k^{TG}$. Let $\sup_n$ denote $\sup_{n \geq 1}$. To analyze the asymptotic behavior of the test under local alternatives, we need to modify Assumptions A.1-A.3 as follows.

**Assumption B.1.** (i) $\{(Y_t', Z_{k,t}'): (Y_{n,t}, Z_{n,k,t}'): t \geq 1, n \geq 1\}$ is an $\alpha$–mixing sequence with mixing coefficients $\alpha(l) = O(l^{-C_0})$, for some $C_0 > \max\{(q-1)(q+1), 1 + 2/\delta\}$ and for $k = 1, \ldots, l$, where $q$ is an even integer that satisfies $q > 3(L_{\max} + 1)/2$, with $L_{\max} = \max\{L_1, \ldots, L_l\}$ and $\delta$ a positive constant.

(ii) For $k = 1, \ldots, l$, $m_k(Z_{k,t}, \beta_k)$ is differentiable, a.s., with respect to $\beta_k$, in the neighborhood $\Theta_{k0}$ of $\beta_{k0}$, with $M_k(Z_{k,t}, \beta) \equiv (\partial/\partial \beta)m_k(Z_{k,t}, \beta)$ satisfying $\sup_n \sup_{\beta \in \Theta_{k0}} \|M_k(Z_{k,t}, \beta)\|_2 < \infty$, for all $t \geq 1$.

(iii) The conditional distribution, $F_{k,n}(\cdot|Z_{k,t})$, of $e_{k,t}$ given $Z_{k,t}$ has bounded density with respect to the Lebesgue measure, a.s., and $\|e_{k,t}\|_{2+\delta} < \infty$ for $k = 1, \ldots, l$, $t \geq 1$ and all $n \geq 1$.

**Assumption B.2.** For $k = 1, \ldots, l$ and $t = R, \ldots, T$, $\hat{\beta}_{k,t}$ satisfies $\hat{\beta}_{k,t} - \beta_{k0} = B_k(t)H_k(t)$, where $B_k(t)$ is a $P_k \times L_k$ matrix and $H_k(t)$ is $L_k \times 1$, with

(i) $B_k(t) \to B_k$, a.s., where $B_k$ is a matrix of rank $P_k$.

(ii) $H_k(t) = t^{-1} \sum_{s=1}^{t} h_{k,s}, R^{-1} \sum_{s=-R+1}^{t} h_{k,s}$ and $R^{-1} \sum_{s=1}^{R} h_{k,s}$ for the recursive, rolling, and fixed schemes respectively, where $h_{k,s} \equiv h_{k,s}(\beta_{k0})$.

(iii) $\sqrt{n}E(h_{k,s}(\beta_{k0})) \to m_k$.

(iv) $\sup_n ||h_{k,s}(\beta_{k0})||_{2+\delta} < \infty$, for some $\delta > 0$.

**Assumption B.3.** (i) The function $F_{k,n}(x, \beta)$ is differentiable with respect to $\beta$ in a neighborhood, $\Theta_{k0}$, of $\beta_{k0}$, for $k = 1, \ldots, l$.

(ii) For $k = 1, \ldots, l$, and for all sequences of positive constants, $\{\xi_n : n \geq 1\}$, such that $\xi_n \to 0$,

$\sup_{x \in \mathcal{X}} \sup_{\beta : ||\beta - \beta_{k0}|| \leq \xi_n} ||\partial F_{k,n}(x, \beta)/\partial \beta - \Delta_{k0}(x)|| = O(\xi_n^{\eta})$, for some $\eta > 0$, where $\Delta_{k0}(x) = \lim_{n \to \infty} \Delta_{k,0,n}(x)$, with $\Delta_{k,0,n}(x) = (\partial F_{k,n}(x, \beta_{k0}))$.

(iii) $\sup_n, \sup_{x \in \mathcal{X}} ||\Delta_{k,0,n}(x)|| < \infty$ for $k = 1, \ldots, l$.

Note that Assumption B.2 implies that the asymptotic distribution of $\sqrt{n} (\hat{\beta}_{k,t} - \beta_{k0})$ has mean $m_k$, which might be non-zero under the local alternatives. Nevertheless, this has no effect on the asymptotic distribution of $TG_n$, as can be seen from the following theorem.

**Theorem 4.2** Suppose that Assumptions B.1-B.3 and A.4 hold. Then, under the local alternatives in (4.1),

$$TG^+_n \Rightarrow \max_{k=2, \ldots, l} \sup_{x \in B^+_k} \left[ \bar{g}_k(x) + \Delta_{k0}(x)' B_k m_k - \Delta_{10}(x)' B_1 m_1 + \mu_k(x) \right],$$

$$TG^-_n \Rightarrow \max_{k=2, \ldots, l} \sup_{x \in B^-_k} \left[ \bar{g}_k(x) + \Delta_{k0}(x)' B_k m_k - \Delta_{10}(x)' B_1 m_1 + \mu_k(x) \right],$$

where $\mu_k(x) = \delta_k(x) - \delta_1(x)$, using the notation defined in Section 3.
This result implies that the asymptotic local power of the $TG^+_n (TG^-_n)$ test based on the stationary bootstrap critical values is given by the following corollary.

**Corollary 4.3** Suppose that Assumptions B.1-B.3 and A.5-A.6 hold and that $(n/R) \log \log R \to 0$, as $T \to \infty$. Then, under the local alternatives,

$$
P(TG^+_n > q^{G+}_{n,TG}(1-\alpha)) - P(TG^+_n > q^{G+}(1-\alpha)) \to 0,
$$

$$
P(TG^-_n > q^{G-}_{n,TG}(1-\alpha)) - P(TG^-_n > q^{G-}(1-\alpha)) \to 0,
$$

as $T \to \infty$, where $q^{G+}_{n,TG}(1-\alpha)$ and $q^{G-}_{n,TG}(1-\alpha)$ are as defined in Section 3.2, $TG^+_n = \max_{k=2,...,T} \sup_{x \in B^+_k} [\gamma_k(x) + \Delta_{k0}(x)'B_k m_k - \Delta_{k1}(x)'B_1 m_1 + \mu_k(x)]$, $TG^-_n = \max_{k=2,...,T} \sup_{x \in B^-_k} [\gamma_k(x) + \Delta_{k0}(x)'B_k m_k - \Delta_{k1}(x)'B_1 m_1 + \mu_k(x)]$, and $q^{G+}(1-\alpha)$ and $q^{G-}(1-\alpha)$ denote the $(1-\alpha)$-th quantiles of the distributions of $TG^+_n$ and $TG^-_n$, respectively.

5 Extensions

Previously, it has been assumed that the underlying process is stationary. However, in some applications, this assumption must be relaxed, due to the presence of heterogeneity. For this reason, asymptotic theory under heterogeneity that is induced by distributional change over time is discussed in this section.

Denote $U_t = (Y_t, Z_{1,t}', ..., Z_{l,t}')'$, as before, and $Z_t = (Z_{1,t}', ..., Z_{l,t}')'$. Define $\mathcal{I}_t = \sigma(Z_{t+\tau}, ..., Z_{t+1}, U_t, U_{t-1}, ...)$, where $\tau$ is the forecast horizon of interest. Consider a situation where $l \geq 2$ alternative models are used to forecast the variable of interest, $\tau$ steps ahead, say $Y_{t+\tau}$. At time $t$, forecasts are based on the information set $\mathcal{I}_t$. For $t \geq R$, denote the $l$ forecasts by $\hat{Y}_{k,t+\tau} = m_k(Z_{t+\tau}, \hat{\beta}_{k,t})$, $k = 1, ..., l$, where each $m_k$ is a measurable function and $\hat{\beta}_{k,t}$ is constructed at time $t$ by using the most recent $R$ observations. Let $\{e_{k,t+\tau} : t \geq R\}$ be the out-of-sample forecast errors from the $k$-th competing model, i.e., $e_{k,t+\tau} = Y_{t+\tau} - \hat{Y}_{k,t+\tau}$. Further, denote $F_{k,t}(\cdot)$ and $F_{k,t}(\cdot | \mathcal{I}_t)$ as the distribution of $e_{k,t+\tau}$ and the conditional distribution of $e_{k,t+\tau}$ given $\mathcal{I}_t$, respectively. Also assume that predictions are made for $n$ periods, indexed from $R$ to $T$, so that $n = T - R + 1$, as above.

Now, change the definition of GL and GC forecast superiority given in Section 2 as follows.

**Definition 5.1** A sequence of forecasting errors $\{e_{1,t+\tau}, t \geq R\}$ General-Loss (GL) outperforms $\{e_{2,t+\tau}, t \geq R\}$, denoted as $e_1 \succeq_G e_2$, if

$$
\lim_{n \to \infty} n^{-1} \sum_{t=R}^{T} E[L(e_{1,t+\tau}) - L(e_{2,t+\tau})] \leq 0,
$$

for all $L \in \mathcal{L}_G$. A sequence of forecasting errors $\{e_{1,t+\tau}, t \geq R\}$ Convex-Loss (CL) outperforms...
\( \{e_{2,t+\tau}, t \geq R \} \), denoted as \( e_1 \geq_C e_2 \), if
\[
\lim_{n \to \infty} n^{-1} \sum_{t=1}^{T} E[L(e_{1,t+\tau}) - L(e_{2,t+\tau})] \leq 0,
\]
for all \( L \in \mathcal{L}_C \).

Modify Propositions 2.2 and 2.3 to accommodate data heterogeneity, as follows.

**Proposition 5.2** \( \lim_{n \to \infty} n^{-1} \sum_{t=1}^{T} E[L(e_{1,t+\tau}) - L(e_{2,t+\tau})] \leq 0 \), for all \( L \in \mathcal{L}_C \), if and only if
\[
\lim_{n \to \infty} n^{-1} \sum_{t=1}^{T} [F_{2,t}(x) - F_{1,t}(x)] sgn(x) \leq 0,
\]
for all \( x \in \mathcal{X} \), where \( \mathcal{X} \) is the union of the supports of \( e_1 \) and \( e_2 \).

**Proposition 5.3** Suppose that \( \int_{-\infty}^{\infty} (F_{1t}(u) - F_{2t}(u)) du \ 1(x < 0) \) and \( \int_{-\infty}^{\infty} (F_{2t}(u) - F_{1t}(u)) du \ 1(x \geq 0) \) are well defined, for each \( x \in \mathcal{X} \).

Then \( \lim_{n \to \infty} n^{-1} \sum_{t=1}^{T} E[L(e_{1,t+\tau}) - L(e_{2,t+\tau})] \leq 0 \), for all \( L \in \mathcal{L}_C \), if and only if
\[
\lim_{n \to \infty} n^{-1} \sum_{t=1}^{T} \int_{-\infty}^{x} (F_{1,t}(s) - F_{2,t}(s)) ds \ 1(x < 0) + \int_{x}^{\infty} (F_{2,t}(s) - F_{1,t}(s)) ds \ 1(x \geq 0) \leq 0,
\]
for all \( x \in \mathcal{X} \).

**Remarks.** First, without the stationarity assumption, we compare the average risks for competing forecasting models where the average is taken over all \( n \) predictions. If \( \{e_{i,t+\tau}, t \geq R \}, i = 1, 2 \), are strictly stationary, one can denote the common marginal distributions as \( F_i, i = 1, 2 \), yielding Propositions 2.2 and 2.3. Second, let \( \bar{F}_k(\cdot) = \lim_{n \to \infty} n^{-1} \sum_{t=1}^{T} F_{k,t}(\cdot), k = 1, \ldots, l \). Then \( e_1 \geq_C e_2 \) implies that \( \bar{F}_1(0) = \bar{F}_2(0) \). Third, consider defining conditional analogues of GL and CL forecast superiority by replacing \( E[\cdot] \) with \( E[\cdot|I_t] \) and \( F_{kt}(\cdot) \) with \( F_{kt}(\cdot|I_t) \) in the above definitions. In this case, different sequences of forecast errors are evaluated by comparing their average conditional risks.\(^{4}\)

For \( k = 1, \ldots, l \), denote \( F_{k,t}(x) = P(e_{k,t+\tau} \leq x) \) and \( \bar{F}_{k,n}(x) = n^{-1} \sum_{t=1}^{T} 1(e_{k,t+\tau} \leq x) \). Now , define the following functionals of the joint distribution, \( F_i(x_1, \ldots, x_l) \) of \( (e_{1,t+\tau}, \ldots, e_{l,t+\tau}) \), \( t \geq R \),

\[
HTG^+ = \max_{k=2, \ldots, l, x \in \mathcal{X}^+} \sup H G_k(x), \quad (5.1)
\]
\[
HTG^- = \max_{k=2, \ldots, l, x \in \mathcal{X}^-} \sup H G_k(x), \quad (5.2)
\]
\[
HTC^+ = \max_{k=2, \ldots, l, x \in \mathcal{X}^+} \sup H C_k(x), \quad (5.3)
\]
\[
HTC^- = \max_{k=2, \ldots, l, x \in \mathcal{X}^-} \sup H C_k(x), \quad (5.4)
\]

\(^{4}\)We conjecture that the asymptotic properties in this case can be derived by using the results in Harel and Puri (1999). Conditional forecast superiority is a stronger property than its unconditional analogue. However, it is difficult to find empirical support for this property, and thus the topic is left to future research.
where \( HG_k(x) = \lim_{n \to \infty} n^{-1} \sum_{t=R}^{T} [F_k,t(x) - F_{1,t}(x)]sgn(x) \), and
\[
HC_k(x) = \lim_{n \to \infty} n^{-1} \sum_{t=R}^{T} \left[ \int_{-\infty}^{x} (F_{1,t}(s) - F_{k,t}(s))ds1(x < 0) + \int_{x}^{\infty} (F_{k,t}(s) - F_{1,t}(s))ds1(x \geq 0) \right].
\]

Without loss of generality, also assume that the union of the supports of all forecast error sequences, \( \mathcal{X} \), is bounded. The hypotheses of interest can now be stated as
\[
H_0^{HTG} : \text{HTG}^+ \leq 0 \cap \text{HTG}^- \leq 0 \text{ vs. } H_1^{TG} : \text{HTG}^+ > 0 \cup \text{HTG}^- > 0
\]
and
\[
H_0^{HTC} : \text{HTC}^+ \leq 0 \cap \text{HTG}^- \leq 0 \text{ vs. } H_1^{TC} : \text{HTC}^+ > 0 \cup \text{HTC}^- > 0.
\]

In formulating the null hypothesis \( H_0^{HTG} \), define \( \{e_{1,t+\tau}, t \geq R\} \) to be the benchmark forecast error or the corresponding model (model 1) as the benchmark model. Interest lies in determining whether there exists some forecasting model superior to this model. Failure to reject the null implies that no competing forecast GL/CL outperforms the benchmark forecast.

The test statistics that we consider in this context are based on the empirical analogues of (5.1) to (5.4). They are defined as follows.
\[
\text{HTG}^+_n = \max_{k=2, \ldots, l} \sup_{x \in \mathcal{X}^+} \sqrt{n}HG_k(x),
\]
\[
\text{HTG}^-_n = \max_{k=2, \ldots, l} \sup_{x \in \mathcal{X}^-} \sqrt{n}HG_k(x)
\]
\[
\text{HTC}^+_n = \max_{k=2, \ldots, l} \sup_{x \in \mathcal{X}^+} \sqrt{n}HC_k(x),
\]
\[
\text{HTC}^-_n = \max_{k=2, \ldots, l} \sup_{x \in \mathcal{X}^-} \sqrt{n}HC_k(x),
\]
where \( HG_{k,n}(x) = (F_{k,n}(x) - F_{1,n}(x))sgn(x) \) and \( HC_{k,n}(x) = \int_{-\infty}^{x} (F_{1,n}(s) - F_{k,n}(s))ds1(x < 0) + \int_{x}^{\infty} (F_{k,n}(s) - F_{1,n}(s))ds1(x \geq 0) \).

Theoretical analysis of these statistics requires the following modifications to the assumptions in Section 3.

**Assumption HA.1.** (i) \( \{(Y_t, Z_{k,t}'): t \geq 1\} \) is an \( \alpha \)-mixing sequence with mixing coefficients \( \alpha(l) = O(l^{-C_0}) \), for some \( C_0 > (q-1)(q+1) \), for \( k = 1, \ldots, l \), where \( q \) is an even integer that satisfies \( q \geq 2 \).

(ii) For all \( t \geq R \), the distribution \( F_{k,t}(\cdot) \) of \( e_{k,t+\tau} \) has bounded density with respect to the Lebesgue measure, a.s., and \( \sup_{t \geq R} E|e_{k,t+\tau}| < \infty \), for \( k = 1, \ldots, l \).

**Assumption HA.4.** \( R \) is fixed, so that \( \lim_{T \to \infty} (n/R) = \infty \).

For the \( \text{HTC}_n \) test we additionally require the following modification of Assumption HA.1.

**Assumption HA.1.* (i) \( \{(Y_t, Z_{k,t}'): t \geq 1\} \) is an \( \alpha \)-mixing sequence with mixing coefficients \( \alpha(l) = O(l^{-C_0}) \), for some \( C_0 > rq/(r-q) \), for \( k = 1, \ldots, l \) and \( r > q \geq 2 \).
(ii) $\sup_{t \geq R} ||e_{k,t+r}||_r < \infty$ for $k = 1, \ldots, l$.

To derive the asymptotic null distributions of the test statistics, define the empirical processes in $x$

\[ v_{k,n}^{hg}(x) = \frac{1}{\sqrt{n}} \sum_{t=R}^{T} \{1(e_{k,t+r} \leq x) - F_{k,t}(x)\} \text{sgn}(x) \] and

\[ v_{k,n}^{hc}(x) = \frac{1}{\sqrt{n}} \sum_{t=R}^{T} \left\{ \int_{-\infty}^{x} [1(e_{k,t+r} \leq s) - F_{k,t}(s)] ds1(x < 0) \
+ \int_{x}^{\infty} [1(e_{k,t+r} \leq s) - F_{k,t}(s)] ds1(x \geq 0) \right\}. \]

Let $\widetilde{h}_g(k)\cdot$ be a mean zero Gaussian process with covariance function given by

\[ \Omega_{k}^{hg}(x_1, x_2) = \lim_{n \to \infty} E \left( v_{k,n}^{hg}(x_1) - v_{1,n}^{hg}(x_1) \right) \left( v_{k,n}^{hg}(x_2) - v_{1,n}^{hg}(x_2) \right). \]

Analogously, define $\widetilde{h}_c(k)\cdot$ to be a mean zero Gaussian process with covariance function given by

\[ \Omega_{k}^{hc}(x_1, x_2) = \lim_{n \to \infty} E \left( v_{k,n}^{hc}(x_1) - v_{1,n}^{hc}(x_1) \right) \left( v_{k,n}^{hc}(x_2) - v_{1,n}^{hc}(x_2) \right). \]

The limiting null distributions of the test statistics are given in the following theorem.

**Theorem 5.4** (a) Suppose that Assumptions HA.1 and HA.4 hold. Then, under $H_0^{HTG+}$,

\[ HTG_{+}^{n} \Rightarrow \max_{k=2, \ldots, l} \sup_{x \in \mathcal{B}_{k}^{hg+}} \widetilde{h}_g(k) \text{ if } HTG^{+} = 0 \]

\[ \Rightarrow -\infty \text{ if } HTG^{+} < 0, \] \hspace{1cm} (5.7)

and under $H_0^{HTG-}$,

\[ HTG_{-}^{n} \Rightarrow \max_{k=2, \ldots, l} \sup_{x \in \mathcal{B}_{k}^{hc-}} \widetilde{h}_c(k) \text{ if } HTG^{-} = 0 \]

\[ \Rightarrow -\infty \text{ if } HTG^{-} < 0, \] \hspace{1cm} (5.8)

where $\mathcal{B}_{k}^{hg+} = \{x \in X^+: \mathcal{F}_1(x) = \mathcal{F}_k(x)\}$ and $\mathcal{B}_{k}^{hg-} = \{x \in X^-: \mathcal{F}_1(x) = \mathcal{F}_k(x)\}$.

(b) Suppose that Assumptions HA.1* and HA.4 hold. Then, under $H_0^{HTC+}$,

\[ HTC_{+}^{n} \Rightarrow \max_{k=2, \ldots, l} \sup_{x \in \mathcal{B}_{k}^{hc+}} \widetilde{h}_c(k) \text{ if } HTC^{+} = 0 \]

\[ \Rightarrow -\infty \text{ if } HTC^{+} < 0, \] \hspace{1cm} (5.10)

and under $H_0^{HTC-}$,

\[ HTC_{-}^{n} \Rightarrow \max_{k=2, \ldots, l} \sup_{x \in \mathcal{B}_{k}^{hc-}} \widetilde{h}_c(k) \text{ if } HTC^{-} = 0 \]

\[ \Rightarrow -\infty \text{ if } HTC^{-} < 0, \] \hspace{1cm} (5.11)

where $\mathcal{B}_{k}^{hc+} = \{x \in X^+: \int_{x}^{\infty} (\mathcal{F}_1(s) - \mathcal{F}_k(s)) ds = 0\}$ and $\mathcal{B}_{k}^{hc-} = \{x \in X^-: \int_{-\infty}^{x} (\mathcal{F}_k(s) - \mathcal{F}_1(s)) ds = 0\}$.
The asymptotic null distributions of $\text{HTG}_n^+$ ($\text{HTG}_n^-$) and $\text{HTC}_n^+$ ($\text{HTC}_n^-$) depend on the distribution functions $\{F_k(\cdot) : k = 1, \ldots, l\}$. This implies that the asymptotic critical values for $\text{HTG}_n^+$ ($\text{HTG}_n^-$) and $\text{HTC}_n^+$ ($\text{HTC}_n^-$) cannot be tabulated. However, Theorem 2.2 in Goncalves and White (2004) applies in this case, and their stochastic equicontinuity result for heterogeneous dependent variables can thus be used to establish the validity of block bootstrap.\footnote{We cannot use the stationary bootstrap in this case because it assumes stationarity of the underlying process. Nevertheless, subsampling procedure can alternatently be used. However, simulation results show that size and power properties are poor when subsampling is used.}

Associated global and local power properties can also be established as in Section 4 (for brevity, we do not repeat the arguments).

6 Simulation Evidence

In this section, we first discuss results of simulations conducted in order to evaluate the finite sample performance GL and CL forecast superiority tests when there are only two competing sequences of forecast errors. We discuss the results of a Monte Carlo experiment designed to examine the finite sample performance of the tests when there are more than two competing sequences of forecast errors, under stationarity. Finally, a small Monte Carlo experiment is conducted to check the performance of the tests in the case where the underlying process is not stationary.

When computing the suprema in $\text{TG}_n^+$, $\text{TG}_n^-$, $\text{TC}_n^+$, and $\text{TC}_n^-$, we take a maximum over an equally spaced grid of size $[1.5n^{0.6}]$, over a 98% range of the pooled empirical distribution; that is, we take the 1% and 99% percentiles of this empirical distribution and then form an equally spaced grid between these two extremes. For each experiment we use 1000 replications. We set the number of bootstrap resamples as $B = 300$. Additionally, six different values of the smoothing parameter, $S_n$, are examined for each sample size $n \in \{100, 500, 1000\}$ for the pairwise comparison case, and four different values of $S_n$ are examined for each sample size $n \in \{250, 500, 1000\}$ for the multiple comparison and heterogeneity cases, where values of $S_n$ are equally spaced on the interval $[n^{-0.4}, n^{-0.1}]$. For each $n$, rejection probabilities of the tests with nominal size 0.1 are reports. Results corresponding to different nominal sizes are qualitatively similar and are not reported.

6.1 Pairwise comparisons: stationary case

We first study the following three data generating processes (DGPs) with independent forecast errors and i.i.d. observations:

DGP1: $e_{1t} - \text{i.i.d.} \ N(0, 1)$ and $e_{2t} - \text{i.i.d.} \ N(0, 1)$.

DGP2: $e_{1t} - \text{i.i.d.} \ \text{Uniform} (-2, 2)$ and $e_{2t} - \text{i.i.d.} \ N(0, 1)$.

DGP3: $e_{1t} - \text{i.i.d.} \ \text{Beta}(1,2)$ and $e_{2t} - \text{i.i.d.} \ \text{Beta}(2,4)$; where both forecast error sequences are recentered around their common mean of 1/3.
It is easy to verify that the first design allows us to examine finite sample size properties for both forecast superiority tests, and is a “least favorable” case. The second and third designs allow us to examine finite sample power for both tests.

In the next three DGPs, we allow the two forecast errors to be dependent on each other with non-independent observations. Following Klecan, McFadden, and McFadden (1991), we generate $e_{kt}$ according to

$$e_{kt} = (1 - \lambda)(\sqrt{\rho e_{0t}} + \sqrt{1 - \rho} e_{kt}) + \lambda e_{k,t-1},$$

where $(e_{0t}, e_{1t}, e_{2t})$ are i.i.d. but have different marginals in different DGPs. The parameters $\lambda = \rho = 0.1$ determine the mutual dependence of $e_{1t}$ and $e_{2t}$ and their autocorrelations. This scheme produces autocorrelated and mutually dependent forecast errors, and we consider three such DGPs.

DGP4: $(\tilde{e}_{0t}, \tilde{e}_{1t}, \tilde{e}_{2t})$ are i.i.d $N(0, I_3)$;
DGP5: $\tilde{e}_{1t} \sim i.i.d N(0, 1.5)$ and $\tilde{e}_{kt} \sim i.i.d N(0, 1)$, for $k = 0$ and 2;
DGP6: $\tilde{e}_{0t} \sim i.i.d. Beta(1,1)$, $\tilde{e}_{1t} \sim i.i.d. Beta(1,2)$, and $\tilde{e}_{2t} \sim i.i.d. Beta(2,4)$; where and all are recentered around their population means, i.e., 1/2, 1/3 and 1/3, respectively.

As above, DGP4 is our “null” model, while DGPs 5 and 6 are our “alternative” models. A comparison of the simulation results based on DGP1 and DGP4 will yield insight into the effect of autocorrelation and mutual dependence on the level of the tests. Similarly, a comparison of the simulation results based on DGP3 and DGP6 will yield insight into the effect of autocorrelation and mutual dependence on the power of the tests.

As above, DGP4 is our “null” model, while DGPs 5 and 6 are our “alternative” models. A comparison of the simulation results based on DGP1 and DGP4 will yield insight into the effect of autocorrelation and mutual dependence on the level of the tests. Similarly, a comparison of the simulation results based on DGP3 and DGP6 will yield insight into the effect of autocorrelation and mutual dependence on the power of the tests.

Simulation results for the above DGPs are reported in Table 1. The main entries in the table are the rejection frequencies, as discussed above. From the left panel of the table, observe that for our small sample size ($n = 100$), the test is over-sized for some values of $S_n$ and has substantial power in detecting deviations from the null. Given the nature of the testing problem considered in this paper, a sample size of 100 observations is very small indeed. A comparison between the results for DGP1 (3) and DGP4 (6) indicates that the level (power) of the test is somewhat sensitive to the degree of mutual and serial dependence in the data when the sample size is small. However, test power quickly jumps to 100% as the sample size rises, and indeed both level and power are well behaved for large sample sizes, say $n = 1000$. Similar conclusions follow for the test of $CL$ forecast superiority, as shown in the right panel of Table 1.

6.2 Multiple comparisons: stationary case

For the sake of brevity, we consider independent forecasts and i.i.d. observations. For the following eight data generating processes (DGPs), we fix $e_{1t} \sim i.i.d N(0, 1)$ but let the number of competing forecasting models vary:

DGP7: $e_{kt} \sim i.i.d. N(0, 1), k = 2, 3$.
DGP8: $e_{kt} \sim i.i.d. N(0, 1), k = 2, 3, 4, 5$. 

21
DGP9: \( e_{kt} \sim i.i.d.N(0,1) \), \( k = 2, 3, 4, 5 \) and \( e_{kt} \sim i.i.d.N(0,1.2^2) \), \( k = 6, 7, 8, 9 \).

DGP10: \( e_{kt} \sim i.i.d.N(0,0.8^2) \), \( k = 2, 3, 4, 5 \) and \( e_{kt} \sim i.i.d.N(0,1.2^2) \), \( k = 6, 7, 8, 9 \).

DGP11: \( e_{kt} \sim i.i.d.N(0,0.8^2) \), \( k = 2, 3 \).

DGP12: \( e_{kt} \sim i.i.d.N(0,0.6^2) \), \( k = 2, 3 \).

DGP13: \( e_{kt} \sim i.i.d.N(0,0.8^2) \), \( k = 2, 3, 4, 5 \).

DGP14: \( e_{kt} \sim i.i.d.N(0,0.6^2) \), \( k = 2, 3, 4, 5 \).

Here, DGPs 7-9 are our “null” models, while DGPs 10-14 are our “alternative” models. DGPs 7 and 8 correspond to the least favorable elements in the null and the theory of our stationary bootstrap test applies directly to this case. In DGP9, the benchmark model outperforms all of the competing models, while in DGP10, half of the competing models outperform the benchmark model and the other half underperform.

Table 2 summarizes results for the null hypotheses \( H_{TG}^0 : TG^+ \cap TG^- \leq 0 \), where \( e_1 \) is taken as the benchmark forecast error. For all sample sizes in our investigation, the tests have good size performance for DGPs 7 and 8, where the nulls are least favorable to the alternatives, while the tests are mostly under-sized for DGP 9, where the nulls are not least favorable to the alternatives. This verifies our theory, which predicts that the stationary bootstrap works well for least favorable nulls. Now, consider the power performance of the test. Interestingly, for all cases (i.e. DGPs 10-14), the test has a good power performance. Note also that an inclusion of poorer models in the test improves the power of the test, as expected.

Table 3 summarizes results for the null hypotheses \( H_{TC}^0 : TC^+ \cap TC^- \leq 0 \), where \( e_1 \) is taken as the benchmark forecast error. The superiority test continues to perform well. A comparison of Tables 2 and 3 indicates that we have more chance to correctly reject the null \( H_{TC}^0 : TC \leq 0 \) than the null \( H_{TG}^0 : TG \leq 0 \). This is consistent with the theory that GL forecast superiority implies CL forecast superiority.

### 6.3 Pairwise comparisons: heterogeneous case

In this subsection, we explore the case where forecast comparison is carried out for two competing sequences of heterogeneous forecast errors. For the sake of brevity, we study a small set of DGPs. In particular, for DGPs 15 through 18, \( e_{it} \sim a_{it}N(0,1) \), for \( i = 1, 2 \) and \( t \geq 1 \), where \( \{a_{1t}\} \) is chosen to be the infinite repetition of the sequence \( \{1 1 1 2.5 1.25 1.25 0.75 0.75 0.75 1 1 1\} \) and \( \{a_{2t}\} \) to be the infinite repetition of the sequence as follows:

DGP15: \( a_{2t} = a_{1t} \).

DGP16: \( \{1 1 1 2.5 1.25 1.25 1 1 1 0.75 0.75 0.75 \} \).

DGP17: \( \{1 1 1 0.65 0.65 0.65 0.5 0.5 0.5 0.8 0.8 0.8\} \).

DGP18: \( a_{2t} = 0.75a_{1t} \).
Clearly, the first two designs are “null” models for both GL and CL forecast superiority tests and they are both “least favorable” to the alternatives. The last two designs are “alternative” models.

Table 4 summarizes results for the null hypotheses $H_{0}^{HTG}: HTG^+ \leq 0 \land HTG^- \leq 0 \land HTC^+$, where $\{e_{1,t}\}$ is taken as the benchmark forecast error. We use the block bootstrap, where the block size is chosen to be equally spaced on the interval $[2n^{0.2},2n^{0.4}]$. Overall, the sizes for the testing procedure behave reasonably well, despite the fact that the test is a little upward biased when sample size is small. Additionally, tests based on the use of the block bootstrap seem to have good power properties for multiple comparison of forecasting models with heterogeneous forecast errors.

7 Empirical Illustration

In this section forecast superiority tests are used to evaluate forecast errors resulting from two sets of forecast models for spot exchange rates among 6 industrialized countries. This study is for illustrative purpose only, and all forecast models are stylized, involving no estimation. Due to this simplistic approach, we do not need to distinguish between in-sample and out-of sample forecasts.

7.1 Data and models

The data consist of six 3-month-ahead forward rates and spot rates for the Canadian Dollar (CAD), French Franc (FRF), German Mark (GEM), Japanese Yen (JPY), Swiss Franc (CHF) and British Pound (GBP), relative to the US dollar. The data were obtained from Datastream for daily sample period from Jan. 1, 1992 through Feb. 28, 2002, at which point the euro became the sole legal tender in all euro area countries. This group of countries is the same as that studied in Hunter and Timme (1992). In summary, the dataset that we analyze is comprised of 2652 observations. However, due to national holidays and a variety of other reasons, some observations are missing. If the observations for a country is missing, we simply deleted it. This results in varying numbers of observations for each country, as follows: 2556 for CAD, 2620 for FRF, 2560 for GEM, 2617 for JPY, 2579 for CHF, and 2541 for GBP.

Our forecast comparison is based upon forecast errors resulting from two sets of forecasting models. We refer to the first set of forecasting models as “Forward” models. In these models, forward rates are used to predict the future spot rates. Namely, $E_t(X_{t+\tau}) = F_{t,\tau}$, where $X_{t+\tau}$ is the spot exchange rate at time $t + \tau$, $F_{t,\tau}$ is the $\tau$-period ahead forward exchange rate observed at time $t$ and $E_t(X_{t+\tau})$ is the expectation of the spot rate at time period $t + \tau$, conditional on information available at time $t$. If the “unbiasedness hypothesis” is true, given conditions of rational expectations and risk neutrality, then we should expect that the $\tau$-period ahead forward exchange rate is the best predictor of the future spot rate

---

6 We considered various different sample periods, with little change in our empirical findings.
at time $t + \tau$.\footnote{Here we follow Hunter and Timme (1992) and use the levels of the exchange rates in all of our calculations. We also tried to use logarithms of exchange rates, with similar empirical findings.} The second set of forecast models are termed “Spot” models. It is assumed that the current spot rate is the best forecast of the future spot rate. Namely, $E_t(X_{t+\tau}) = S_t$. There is a large amount of empirical support for this model. See, e.g., Chiang (1986) and Meese and Rogoff (1988), who show that the current rate is a better predictor of the future spot rate than either the forward rate or forecasts from structural and other time series models. In a study closely related to that carried out here, Hunter and Timme (1992) base their analysis on revenues resulting from the adoption of different forecasting models in a hedging framework, and conduct the first and second order stochastic dominance tests on these revenues. Here, we take the alternative approach of carrying out forecast comparison based upon the evaluation of forecast errors. In particular, we implement, tests for GL forecast superiority and CL forecast superiority.

### 7.2 Preliminary analysis

Before conducting forecast superiority tests, we report two traditional measures (mean square forecast error - MSFE and mean absolute forecast error - MAFE) of forecast performance for all models under our investigation (refer to Table 5). Note that both MSFE and MAFE belong to the CL and thus also GL class of loss functions. If the forecast error from one forecasting model has both lower MSFE and MAFE than the other model, one might wonder whether it GL or CL outperforms the other. On the other hand, if one model has lower MSFE while the other model has lower MAFE, and the differences are statistically significant,\footnote{This frequently occurs in practice. For example, the in-sample forecast errors from a least squares regression will have a lower MSFE and higher MAFE than those from a conditional median regression model with the same structure.} we would expect there to be no CL and thus no GL forecast superiority. Inspection of the results in Table 5 indicates that the spot model has lower MSFE and MAFE than the forward model for all countries, with the exception of the UK. The difference is not big though.

Now consider examining the empirical distribution functions (EDFs) for the forecast errors from the two models. For all six countries, the EDFs for the forward forecast error almost coincide with those for the spot forecast error, with some slight differences. To save space, we do not report the results here. To look at the differences between the forward and spot EDFs more clearly, for each country we plot $G_n(x)$ and $C_n(x)$ against $x$, where for $x$, we take 200 equally spaced values between the 1% and 99% percentiles of the pooled empirical distribution for the forward and spot forecast errors, and where $G_n(x)$ and $C_n(x)$ are empirical analogs of $G(x)$ and $C(x)$ defined in (2.1) and (2.2). These plots are given in Figures 1 and 2, for $G_n(x)$ and $C_n(x)$, respectively. Note that both the probability difference in $G_n(x)$ and the integrated probability difference in $C_n(x)$ have been scaled up by $\sqrt{n}$, where $n$ is the sample size. Three cases may result in the examination of these plots.

**Case 1:** If $G_n(x)$ ($C_n(x)$) is significantly larger than 0 for all $x$, we conclude that the forward model
is superior to the spot model in the sense that it GL (CL) outperforms the latter model.

Case 2: If \( G_n(x) \) (\( C_n(x) \)) is significantly smaller than 0 for all \( x \), we conclude that the spot model is superior to the forward model.

Case 3: if \( G_n(x) \) (\( C_n(x) \)) is positive for some values of \( x \) and negative for other values of \( x \), GL (CL) forecast superiority may or may not exist, depending on whether the sign changes are significant.

All of the plots in Figure 1 are consistent with Case 3. Thus, it is of interest to ascertain whether the sign changes are significant or not. Turing to Figure 2, Case 2 pertains to CAD, FRF, and GEM, while Case 3 pertains to the JPY, CHF, and GBP. Note that the magnitude of the integrated probability difference varies substantially from one country to the other. For example, the maximum of the absolute value of \( C_n(x) \) for CAD is roughly \( O_p(1/\sqrt{n}) \) while that for GEM is roughly \( O_p(1) \). We expect that such differences will play a role in our analysis, since the tests have nontrivial power against \( O(1/\sqrt{n}) \) alternatives.

7.3 Tests for forecast superiority

GL and CL test statistics and critical values are constructed following Sections 3 and 6. To be specific, in computing the suprema in \( G_n(x) \) and \( C_n(x) \), we take the maximum over an equally spaced grid of size \( [1.5n^{0.6}] \), on the 98% range of the pooled empirical distribution. Additionally, we choose a total of twelve different values for \( S_n \), which are equally spaced on the interval \( [n^{-0.4}, n^{-0.1}] \).

Figure 3 reports the \( p \)-values associated with testing the null hypotheses \( H^G_{0,S} \): Spot GL outperforms Forward and \( H^G_{0,F} \): Forward GL outperforms Spot. Small \( p \)-values, say, smaller than 0.1, suggest that the corresponding null hypothesis is false. A small \( p \)-value for one test coupled with a large \( p \)-value for the other test indicate that one model is superior to the other. Turning to our findings, first consider the Canadian Dollar. The \( p \)-values for the null \( H^G_{0,F} \) range from 0.11 to 0.33, and the \( p \)-values for the null \( H^G_{0,S} \) are larger than 0.5 for all values of \( S_n \) used, suggesting a failure to reject either null. Statistically speaking, the forward model and the spot model perform equally well in forecasting the future spot rates, in this case. Nevertheless, if one takes into account the magnitude of the \( p \)-values, one might argue that Spot is “better” than Forward. Second, despite the sign changes in \( G_n(x) \) for FRF, GEM, JPY, and CHF, our tests suggest that the Spot GL outperforms Forward for all these countries. This finding is interesting, as it supports earlier findings due to Hunter and Timme (1992) that Spot outperforms Forward when one directly tests for first order stochastic dominance using returns resulting from a hedging based trading strategy applied to these two models. Third, as expected from our preliminary analysis, there is no GL forecast superiority in either direction in the case of GBP.

In Figure 4, we plot the \( p \)-values associated with implementation of our CL forecast superiority tests, i.e. we test \( H^C_{0,S} \) and \( H^C_{0,F} \). Examination of this figure indicates that Spot CL outperforms Forward for CAD, FRF, GEM, JPY and CHF. The tests for CL forecast superiority in the case of GBP are similar.
to results arising when testing GL forecast superiority.

In summary, the key finding of this empirical illustration is that our forecast superiority test results are consistent with the conventional point MSFE and MAPE criteria reported in Table 5. However, while the differences between MSFEs and MAPEs when comparing our two models are quite small and likely statistically insignificant, our forecast superiority tests indicate that Spot is superior to Forward for all loss functions in the GL class, for CAD, FRF, GEM, JPY and CHF. This is important since moment-based criteria only look in a particular direction when evaluating forecast errors, while GL or CL forecast superiority tests are based on the entire distribution of forecast errors and do not require knowledge of the exact form of the loss function. One drawback of our GL and CL forecast superiority tests is that they only offer a partial ranking when the number of models is greater than 2.

8 Concluding Remarks

This paper outlines a novel approach to forecast comparison that yields a forecast ranking that is robust to the choice of loss function. In particular, we introduce the concepts of general-loss (GL) forecast superiority and convex-loss (CL) forecast superiority, and we establish a mapping between GL (CL) superiority and first (second) order stochastic dominance. This allows us to develop a testing procedure based on an out-of-sample generalization of the tests introduced by Linton, Maasoumi and Whang (2005). The asymptotic properties under the null and under sequences of local alternatives are derived, and it is noted that critical values for the limiting distribution cannot be tabulated. In light of this finding, we show first order validity of critical values based on the stationary bootstrap. Furthermore, we have study the extension of our tests to the case of heterogeneous observations. Findings from a small Monte Carlo study show that the suggested tests have good properties, even for moderate sample sizes. Finally, an empirical illustration in which exchange rate models are used to predict future spot rates is presented. While, no clear cut conclusions can be drawn based on the inspection of mean square and mean absolute error forecast accuracy criteria, our tests indicate that a simple spot rate model is GL-superior to an alternative forward rate type model. A limitation of our testing procedure is that our statistics have non-degenerate limiting distributions only over the least favorable case, under the null. Thus, convergence is not uniform within the probability measures in the null hypotheses. As a consequence, the tests are not asymptotically similar, in the sense of not having exact asymptotic size. In a follow up of this paper, Corradi, Jin and Swanson (2015) use recent developments in testing sequences of inequality restrictions (e.g., Andrews and Barwick (2012), Andrews and Shi (2009,2014), Andrews and Soares (2010), and Linton, Song and Whang (2010)) in order to obtain tests for GL/CL superiority which are similar on the boundary of the null hypothesis. Furthermore, they analyze the trade off between similarity on the boundary and power, see e.g. Lee, Andrews (2012) and Lee, Song and Whang (2013, 2014).
Appendix

Proof of Proposition 2.2: Let \( f_1 \) and \( f_2 \) be the densities associated with \( F_1 \) and \( F_2 \). We begin with the IF part.

\[
\int_{-\infty}^{\infty} L(z) (f_1(z) - f_2(z)) \, dz \\
= \int_{-\infty}^{0} L(z) (f_1(z) - f_2(z)) \, dz + \int_{0}^{\infty} L(z) (f_1(z) - f_2(z)) \, dz \\
= L(z) (F_1(z) - F_2(z)) \bigg|_{-\infty}^{0} + L(z) (F_1(z) - F_2(z)) \bigg|_{0}^{\infty} \\
- \int_{-\infty}^{0} L'(z) (F_1(z) - F_2(z)) \, dz - \int_{0}^{\infty} L'(z) (F_1(z) - F_2(z)) \, dz \\
= -\int_{-\infty}^{0} L'(z) (F_1(z) - F_2(z)) \, dz - \int_{0}^{\infty} L'(z) (F_1(z) - F_2(z)) \, dz \\
\leq 0
\]

if \( (F_2(z) - F_1(z)) \sgn(z) \leq 0 \).

We now move to the ONLY IF part. We need to show that whenever, \( G(x) > 0 \) for all \( x \in \Delta \), with \( G(x) = (F_2(x) - F_1(x)) \sgn(x) \), and \( \Delta \) a set of strictly positive Lebesgue measure, there exists function(s) \( L \in \mathcal{L}_G \) such that \( \int_{\Delta} L(z) (f_1(z) - f_2(z)) \, dz > 0 \). In fact, \( \int_{\Delta} L'(z) (F_1(z) - F_2(z)) \, dz > 0 \) and we need a function \( L \) whose derivative \( L' \) puts enough mass on the set \( \Delta \), so that

\[
\int_{\Delta} \left. L'(z) (F_1(z) - F_2(z)) \right|_{>0} \, dz + \int_{\Delta^c} \left. L'(z) (F_1(z) - F_2(z)) \right|_{\leq0} \, dz > 0,
\]

with \( \Delta^c \) being the complement of \( \Delta \).

Proof of Proposition 2.3: We begin with the IF part. From the proof of Proposition 2.2, and by a further integration by parts,

\[
\int_{-\infty}^{\infty} L(z) (f_1(z) - f_2(z)) \, dz \\
= -\int_{-\infty}^{0} L'(z) (F_1(z) - F_2(z)) \, dz - \int_{0}^{\infty} L'(z) (F_1(z) - F_2(z)) \, dz \\
= -L'(z) \int_{-\infty}^{z} (F_1(t) - F_2(t)) \, dt \bigg|_{-\infty}^{0} + \int_{-\infty}^{0} L''(z) \left( \int_{-\infty}^{z} (F_1(t) - F_2(t)) \, dt \right) \, dz \\
+ L'(z) \int_{z}^{\infty} (F_1(t) - F_2(t)) \, dt \bigg|_{0}^{\infty} - \int_{0}^{\infty} L''(z) \left( \int_{z}^{\infty} (F_1(t) - F_2(t)) \, dt \right) \, dz \\
= \int_{-\infty}^{0} L''(z) \left( \int_{-\infty}^{z} (F_1(t) - F_2(t)) \, dt \right) \, dz - \int_{0}^{\infty} L''(z) \left( \int_{z}^{\infty} (F_1(t) - F_2(t)) \, dt \right) \, dz \\
\leq 0,
\]

since \( \int_{-\infty}^{0} (F_1(t) - F_2(t)) \, dt = \int_{0}^{\infty} (F_1(t) - F_2(t)) \, dt = 0, \int_{-\infty}^{z} (F_1(t) - F_2(t)) \, dt \leq 0 \) for all \( z \leq 0 \), and \( \int_{z}^{\infty} (F_1(t) - F_2(t)) \, dt \geq 0 \) for all \( z \geq 0 \).
As for the ONLY IF part, we need to show that whenever, \( C(x) > 0 \) for all \( x \in \Delta \), with \( C(x) \) defined in (2.2) and \( \Delta \) being a set of strictly positive Lebesgue measure, there exists function(s) \( L \in \mathcal{L}_C \) such that
\[
\int_{\mathcal{X}} L(z) (f_1(z) - f_2(z)) \, dz > 0.
\]
Without loss of generality, suppose \( \Delta \subset \mathcal{X}^+ \), then
\[
\int_{\Delta} L''(z) \left( \int_z^\infty (F_1(t) - F_2(t)) \, dt \right) \, dz < 0,
\]
and we need to find a function \( L \in \mathcal{L}_C \) having a second derivative \( L'' \) putting enough weight on \( \Delta \) such that
\[
- \int_{\Delta} L''(z) \left( \int_z^\infty (F_1(t) - F_2(t)) \, dt \right) \, dz + \int_{\Delta^c} L''(z) \left( \int_{-\infty}^z (F_1(t) - F_2(t)) \, dt \right) \, dz > 0.
\]

Hereafter, we let \( P \) denote the probability measure governing the behavior of the time series \( \{U_t\} \). \( C \) or \( \tilde{C} \) is a generic constant which may vary from case to case. \(|| \cdot |||\) denotes the Euclidean norm and \( ||X||_q \) denotes the norm \((E|X|^q)^{1/q}\) for a random variable \( X \). \( \sup_t \) denotes \( \sup_{T \leq t \leq T} \) and the summation \( \sum_t \) denotes \( \sum_{t=R}^T \). “var” and “cov” denote variance and covariance. All limits are taken as \( T \) goes to infinity.

To help present the proofs of our theorems in Sections 3 and 4, we first fix some additional notation. Denote \( \beta = (\beta'_1, \beta'_0, \beta'_t) \), \( \beta_0 = (\beta'_0, \beta'_k) \), \( \beta_t = (\beta'_1, \beta'_k)' \), \( N(\varepsilon) = \{\beta : \|\beta - \beta_0\| \leq \varepsilon\} \) and \( N_k(\varepsilon) = \{\beta_k : \|\beta_k - \beta_{k0}\| \leq \varepsilon\} \). Further, we define
\[
\begin{align*}
f_{k,t+\tau}(x, \beta_t) &= \left( 1 \left( e_{k,t+\tau} \left( \beta_{kt} \right) \leq x \right) - 1 \left( e_{1,t+\tau} \left( \beta_{1t} \right) \leq x \right) \right) \text{sgn}(x), \\
f_{k,t+\tau}(x, \beta_t) &= \int_{-\infty}^x \left( 1 \left( e_{1,t+\tau} \left( \beta_{1t} \right) \leq s \right) - 1 \left( e_{k,t+\tau} \left( \beta_{kt} \right) \leq s \right) \right) \, ds \, 1(x < 0) \\
&\quad + \int_x^{\infty} \left( 1 \left( e_{1,t+\tau} \left( \beta_{1t} \right) \leq s \right) - 1 \left( e_{k,t+\tau} \left( \beta_{kt} \right) \leq s \right) \right) \, ds \, 1(x \geq 0).
\end{align*}
\]
Then we can write
\[
TG_n^+ = \max_{k=2, \ldots, T} \sup_{x \in \mathcal{X}} \sqrt{n}D_{kn}^+(x), \quad TG_n^- = \max_{k=2, \ldots, T} \sup_{x \in \mathcal{X}} \sqrt{n}D_{kn}^-(x),
\]
\[
TC_n^+ = \max_{k=2, \ldots, T} \sup_{x \in \mathcal{X}} D_{kn}^+(x), \quad TC_n^- = \max_{k=2, \ldots, T} \sup_{x \in \mathcal{X}} D_{kn}^-(x)
\]
where \( D_{kn}^g(x) = n^{-1} \sum_t f_{k,t+\tau}(x, \beta_t) \), \( D_{kn}^c(x) = n^{-1} \sum_t f_{k,t+\tau}(x, \beta_t) \). Further, we decompose
\[
\sqrt{n}D_{kn}^i(x) = n^{-1/2} \sum_t \left\{ f_{k,t+\tau}(x, \beta_t) - Ef_{k,t+\tau}(x, \beta) \big| \beta = \beta_t \right\} \\
+ n^{-1/2} \sum_t \{ Ef_{k,t+\tau}(x, \beta) \big| \beta = \beta_t \} - Ef_{k,t+\tau}(x, \beta_0) \\
+ n^{1/2} Ef_{k,t+\tau}(x, \beta_0) \\
\equiv \xi_{k1}(x) + \xi_{k2}(x) + \xi_{k3}(x) \quad \text{for} \quad i = g, c.
\]
where we suppress the dependence of \( \xi_{kj}(\cdot) \) on \( n \) for \( j = 1, 2, 3 \). It is clear that under the nulls \( \xi_{kj}(x) \to -\infty \) as \( T \to \infty \) for \( x \notin B_k^i, \, i = g, c. \)
For the $TG^+_n$ test, our objective is to show that under the null $H^+_0$, for $k = 2, \ldots, l$,
\begin{equation}
\xi_{k1}^q(\cdot) \Rightarrow \tilde{g}_k(\cdot), \quad \text{and}
\end{equation}
\begin{equation}
\xi_{k2}^q(x) = \Delta_{k0}(x)B_kv_k - \Delta_{10}(x)B_1v_0 + o_p(1) \text{ uniformly in } x^+,
\end{equation}
Likewise for the $TG^-_n$, $TC^+_n$ and $TC^-_n$ tests.

**Lemma A.1** Suppose Assumptions A.2 and A.4 hold and let $\alpha \in [0, 0.5)$. Then, for $k = 1, \ldots, l$,
\begin{enumerate}
\item[(a)] $\sup_t n^a H_k(t) \overset{P}{\rightarrow} 0$;
\item[(b)] $\sup_t n^a(\hat{\beta}_k - \beta_{k0}) \overset{P}{\rightarrow} 0$;
\item[(c)] $\sup_t n^{1/2} H_k(t) = o_p(1)$.
\end{enumerate}

**Proof of Lemma A.1.**
The results follow from Lemma A.1 and the proof of Lemma 2.3.2 of McCracken (2000).

The following lemma holds for all $k = 1, \ldots, l$.

**Lemma A.2.** (a) Suppose Assumption A.1 holds. Then, for each $\varepsilon > 0$, there exists $\delta > 0$ such that for all $x, \hat{x} \in \mathcal{X}^-$ or $x, \hat{x} \in \mathcal{X}^+$,
\begin{equation}
\lim_{T \rightarrow -\infty} \sup_{\rho^q_{\mathcal{X}^+}(x, \hat{x}, \beta_k) < \delta} \left\| \frac{p_{k,n}(x, \beta_k) - p_{k,n}(\hat{x}, \hat{\beta}_k)}{q} \right\| < \varepsilon,
\end{equation}
where
\begin{equation}
\rho^q_{\mathcal{X}^+}(x, \hat{x}, \beta_k) = \left\{ E \left[ \left( 1(e_{k,t}(\beta_k) \leq x) - 1(e_{k,t}(\hat{\beta}_k) \leq \hat{x}) \right)^2 \right] \right\}^{1/2}.
\end{equation}

(b) Suppose Assumption A.1* holds. Then, for each $\varepsilon > 0$, there exists $\delta > 0$ such that for all $x, \hat{x} \in \mathcal{X}^-$ or $x, \hat{x} \in \mathcal{X}^+$,
\begin{equation}
\lim_{T \rightarrow -\infty} \sup_{\rho^q_{\mathcal{X}^+}(x, \hat{x}, \beta_k) < \delta} \left\| \frac{p_{k,n}(x, \beta_k) - p_{k,n}(\hat{x}, \hat{\beta}_k)}{q} \right\| < \varepsilon,
\end{equation}
where
\begin{equation}
\rho^q_{\mathcal{X}^+}(x, \hat{x}, \beta_k) = \left\{ E \left[ \int_x^\infty 1(e_{k,t}(\beta_k) \leq s)ds - \int_{-\infty}^x 1(e_{k,t}(\hat{\beta}_k) \leq s)ds \right]^r \right\}^{1/r} 1(x < 0, \hat{x} < 0) + \left\{ E \left[ \int_x^\infty 1(e_{k,t}(\beta_k) > s)ds - \int_x^\infty 1(e_{k,t}(\hat{\beta}_k) > s)ds \right]^r \right\}^{1/r} 1(x \geq 0, \hat{x} \geq 0).
\end{equation}

**Proof of Lemma A.2.** We first prove part (a). Without loss of generality (WLOG), we verify the conditions of Theorem 2.2 in Andrews and Pollard (1994) hold with $Q = q$ and $\gamma = 1$ for the case when $x, \hat{x} \in \mathcal{X}^+$, which is bounded on the real line. The mixing condition is implied by Assumption A.1(i). The bracketing condition also holds by the following argument. Let
\begin{equation}
\mathcal{F}^q_k = \{ 1(e_{k,t}(\beta_k) \leq x) : (x, \beta_k) \in \mathcal{X}^+ \times \Theta_{k0} \}.
\end{equation}
We now show $F_k^{\theta+}$ is a class of uniformly bounded functions satisfying the $L^2$—continuity conditions. Let 
$$
\sup_{(x, \beta_k)} \text{sup } \sup_{(x, \beta_k) \in \mathcal{X}^+ \times \Theta_{k0}, \ |x-x_1| \leq r_1, |\beta_k-\beta_k| \leq r_2, \sqrt{r_1^2 + r_2^2} \leq \bar{r}} \{1(e_{k,t+t+r}(\beta_k) \leq \hat{x}) - 1(e_{k,t+t+r}(\beta_k) \leq x)\}
$$
we have

$$
\sup E \sup_{(x, \beta_k)} |1(e_{k,t+t+r}(\beta_k) \leq \hat{x}) - 1(e_{k,t+t+r}(\beta_k) \leq x)|^2
= E \sup_{(x, \beta_k)} |1(e_{k,t+t+r} \leq m_k(\mathcal{Z}_{k,t+t+r, \beta_k}) - m_k(\mathcal{Z}_{k,t+t+r, \beta_k0}) + \hat{x})
-1(e_{k,t+t+r} \leq m_k(\mathcal{Z}_{k,t+t+r, \beta_k}) - m_k(\mathcal{Z}_{k,t+t+r, \beta_k0}) + x)|
\leq E \sup_{(x, \beta_k)} |\{e_{k,t+t+r} - m_k(\mathcal{Z}_{k,t+t+r, \beta_k}) + m_k(\mathcal{Z}_{k,t+t+r, \beta_k0}) - x| \leq ||M_k(\mathcal{Z}_{k,t+t+r, \beta_k0})||_{r_2 + r_1}
\leq C \sup_{\beta_k \in \Theta_{k0}} E||M_k(\mathcal{Z}_{k,t, \beta_k})||_{r_2 + r_1}
\leq \bar{C}\bar{r}.
$$

where $\beta_k$ lies between $\hat{\beta}_k$ and $\beta_k$. The first inequality is due to the fact $|1(z \leq t) - 1(z \leq 0)| \leq 1(|z| \leq |t|)$ for any scalars $z$ and $t$. The second inequality follows from Assumption A.1(ii), the triangle inequality and the Cauchy-Schwartz inequality. The third inequality holds by Assumptions A.1(ii) and (iii), and $\bar{C} = \sqrt{2}C(\sup_{\beta_k \in \Theta_{k0}} E||M_k(\mathcal{Z}_{k,t, \beta_k})|| \vee 1)$ is finite by Assumption A.1(ii). The desired bracketing condition holds because the $L^2$—continuity condition implies the bracketing number satisfies

$$N(\varepsilon, F_k^{\theta+}) \leq C(1/\varepsilon)^{L_k+1}.$$

The other cases can be done in the same fashion.

To prove part (b), WLOG, we only verify the case for $x_1 \geq 0$ and $x_2 \geq 0$. We show that the result follows from Theorem 3 of Hansen (1996) with $a = L_{\text{max}} + 1$, $\lambda = 1$. Let

$$
F_k^{\theta+} = \{ \int_x^\infty 1(e_{k,t}(\beta_k) > s)ds : (x, \beta_k) \in \mathcal{X}^+ \times \Theta_{k0} \}.
$$

Then the functions in $F_k^{\theta+}$ satisfy the Lipschitz condition:

$$
\left| \int_x^\infty 1(e_{k,t+t+r}(\beta_k) > s)ds - \int_x^\infty 1(e_{k,t+t+r}(\beta_k) > s)ds \right|
= \max \left\{ e_{k,t+t+r} + m_k(\mathcal{Z}_{k,t+t+r, \beta_k0}) - m_k(\mathcal{Z}_{k,t+t+r, \hat{\beta}_k}) - \hat{x}, 0 \right\}
- \max \left\{ e_{k,t+t+r} + m_k(\mathcal{Z}_{k,t+t+r, \beta_k0}) - m_k(\mathcal{Z}_{k,t+t+r, \beta_k}) - x, 0 \right\}
\leq m_k(\mathcal{Z}_{k,t+t+r, \hat{\beta}_k}) - m_k(\mathcal{Z}_{k,t+t+r, \beta_k}) + |\hat{x} - x|
\leq \sqrt{2}(\sup_{\beta_k \in \Theta_{k0}} ||M_k(\mathcal{Z}_{k,t+t+r, \beta_k})|| \vee 1)(||\hat{\beta}_k - \beta_k||^2 + (\hat{x} - x)^2)^{1/2}
$$

30
where the first inequality follows from the fact that \(|\max\{z_1,0\} - \max\{z_2,0\}| \leq |z_1 - z_2|\) and the triangle inequality, and the second inequality holds by Assumption A.1*(ii) and the Cauchy-Schwartz inequality. We have \(\max_k \sup_{\beta_0 \in \Theta_0} \| M_k(Z_{k,t+\tau}, \beta_k) \|_r < \infty\) by Assumption A.1*(ii) which yields the conditions (12) and (13) of Hansen (1996). Finally, the mixing condition (11) in Hansen (1996) holds by Assumption A.1*(i).

**Lemma A.3** Suppose Assumptions A.1, A.1*, and A.4 hold. Denote \(\zeta^i_{k,t+\tau}(x, \beta) = f^i_{k,t+\tau}(x, \beta) - Ef^i_{k,t+\tau}(x, \beta_0) + Ef^i_{k,t+\tau}(x, \beta_0), i = g, c\). Then, for \(k = 2, ..., l\),

(a) \[
\sup_t E \sup_{\beta \in N(n^{-\alpha} \epsilon) \times \mathcal{X}^+} \sup_{\epsilon} \left[ \zeta^i_{k,t+\tau}(x, \beta) \right]^2 \leq Cn^{-\alpha} \epsilon, \\
\sup_t E \sup_{\beta \in N(n^{-\alpha} \epsilon) \times \mathcal{X}^-} \sup_{\epsilon} \left[ \zeta^i_{k,t+\tau}(x, \beta) \right]^2 \leq Cn^{-\alpha} \epsilon, \quad i = g, c
\]

(b) \[
\sup_t E \sup_{\beta, \beta' \in N(n^{-\alpha} \epsilon) \times \mathcal{X}^+} \sup_{\epsilon} \left| \zeta^i_{k,t+\tau}(x, \beta) \zeta^j_{k,t+\tau+j}(x, \beta') \right| \leq \tilde{C} \alpha(j)^d (n^{-\alpha} \epsilon)^2, \\
\sup_t E \sup_{\beta, \beta' \in N(n^{-\alpha} \epsilon) \times \mathcal{X}^-} \sup_{\epsilon} \left| \zeta^i_{k,t+\tau}(x, \beta) \zeta^j_{k,t+\tau+j}(x, \beta') \right| \leq \tilde{C} \alpha(j)^d (n^{-\alpha} \epsilon)^2,
\]

where \(d = 1\) and \(\delta/(2 + \delta)\) for \(i = g\) and \(c\), respectively.

**Proof of Lemma A.3.**

Part (a) holds directly from the proof of Lemma A.2 by taking \(x = x\) and \(q = 2\) and applying the Cauchy-Schwartz inequality.

For part (b), WLOG, we consider the case \(x \geq 0\). Define \(\{x^*, \gamma^*_1, \gamma^*_2\} = \arg\sup_{x \in \mathcal{X}^+} \{x, \gamma_1, \gamma_2 \in N(n^{-\alpha} \epsilon) \} \zeta^i_{k,t+\tau}(x, \gamma_1) \zeta^j_{k,t+\tau+j}(x, \gamma_2)\), where we suppress the dependence of \((x^*, \gamma^*_1, \gamma^*_2)\) on \(i = g\) or \(c\). By the proof of Lemma A.2, it is easy to verify \(\| \zeta^i_{k,t+\tau}(x^*, \gamma^*_1) \|_{2+\delta} \leq \| \sup_{\beta \in N(n^{-\alpha} \epsilon) \times \mathcal{X}} \zeta^i_{k,t+\tau}(x, \beta) \|_{2+\delta} = Cn^{-\alpha} \epsilon\). By Assumptions A.1, A.1* and Corollary 1.1 of Bosq (1996),

\[
|\text{cov}(\zeta^i_{k,t+\tau}(x^*, \gamma^*_1), \zeta^j_{k,t+\tau+j}(x^*, \gamma^*_2))| \\
\leq 4\alpha(j) \sup_{\beta \in N(n^{-\alpha} \epsilon) \times \mathcal{X}^+} \sup_{\epsilon} \zeta^i_{k,t+\tau}(x, \beta) \sup_{\beta \in N(n^{-\alpha} \epsilon) \times \mathcal{X}^+} \sup_{\epsilon} \zeta^j_{k,t+\tau+j}(x, \beta) \\
\leq C \alpha(j)(n^{-\alpha} \epsilon)^2,
\]

and

\[
|\text{cov}(\zeta^c_{k,t+\tau}(x^*, \gamma^*_1), \zeta^c_{k,t+\tau+j}(x^*, \gamma^*_2))| \\
\leq 2(1 + 2/\delta)(2\alpha(j))^{\delta/(2+\delta)} \sup_{\beta \in N(n^{-\alpha} \epsilon) \times \mathcal{X}^+} \sup_{\epsilon} \zeta^c_{k,t+\tau}(x, \beta) \sup_{\beta \in N(n^{-\alpha} \epsilon) \times \mathcal{X}^+} \sup_{\epsilon} \zeta^c_{k,t+\tau+j}(x, \beta) \\
\leq C \alpha(j)^{\delta/(2+\delta)} (n^{-\alpha} \epsilon)^2.
\]
This completes the proof.

**Lemma A.4.** (a) Suppose Assumptions A.1-A.4 hold. Then, we have for \(k = 1, \ldots, l\),

\[
\sup_{x \in X^+} \left| \xi^q_{k1}(x) - \nu^q_{k,n}(x, \beta_{k0}) + \nu^q_{1,n}(x, \beta_{1,0}) \right| \overset{P}{\rightarrow} 0, \quad (A.9)
\]

\[
\sup_{x \in X^-} \left| \xi^q_{k1}(x) - \nu^q_{k,n}(x, \beta_{k0}) + \nu^q_{1,n}(x, \beta_{1,0}) \right| \overset{P}{\rightarrow} 0.
\]

(b) Suppose Assumptions A.1*, A.2, A.3* and A.4 hold. Then, we have for \(k = 1, \ldots, l\),

\[
\sup_{x \in X^+} \left| \xi^c_{k1}(x) - \nu^c_{k,n}(x, \beta_{k0}) + \nu^c_{1,n}(x, \beta_{1,0}) \right| \overset{P}{\rightarrow} 0, \quad (A.10)
\]

\[
\sup_{x \in X^-} \left| \xi^c_{k1}(x) - \nu^c_{k,n}(x, \beta_{k0}) + \nu^c_{1,n}(x, \beta_{1,0}) \right| \overset{P}{\rightarrow} 0.
\]

**Proof of Lemma A.4.** WLOG, we consider the case \(x \geq 0\). Denote \(\xi^i_{k, t+\tau}(x, \beta, t) = f^i_{k, t+\tau}(x, \beta_t) - Ef^i_{k, t+\tau}(x, \beta, t)\), \(i = g, c\), then

\[
\xi^i_{k1}(x) - \nu^i_{1,n}(x, \beta_{1,0}) + \nu^i_{k,n}(x, \beta_{k0}) = n^{-1/2} \sum_i c^i_{k, t+\tau}\left(x, \beta_t\right).
\]

Fix \(\varepsilon_0, \delta > 0\). By Lemma A.1 (b), for all \(\varepsilon > 0\), there exists \(T_0\) such that for all \(T > T_0\),

\[
P \left( \sup_{k} \sup_{n} \|\beta_{k, t} - \beta_{k0}\| > \varepsilon \right) < \delta/2.
\]

It is useful then to note that for all \(T > T_0\) and \(\varepsilon_0 > 0\),

\[
P \left( \sup_{k} \sup_{n} \|\beta_{k, t} - \beta_{k0}\| > \varepsilon_0 \right)
\]

\[
\leq P \left( \sup_{\{\beta_t\} \in N(n^{-\varepsilon}) \in X} \sup_{t} \sum_i c^i_{k, t+\tau}(x, \beta_t) > \varepsilon_0 \right)
\]

\[
+ P \left( \sup_{k} \sup_{n} \|\beta_{k, t} - \beta_{k0}\| > \varepsilon \right) + \delta/2
\]

\[
(A.11)
\]

where \(\{\beta_t\} \equiv \{\beta_t\}_{t \in \mathbb{R}}\) is a nonrandom sequence. Now we show that there exists \(T_1 > T_0\) such that for all \(T > T_1\), the first term on the right hand side (r.h.s.) of (A.11) is less than \(\delta/2\). For the remainder of this proof only, let \(\sum_j\) denote the summation \(\sum_{-n+1 \leq j \neq 0 \leq n-1}\). Applying the Chebyshev’s inequality,
we have

\[
\varepsilon_0^2 P \left( \sup_{\{\beta_i\} \in N^{n-\alpha} \varepsilon} \sup_{x \in X^+} n^{-1/2} \left| \sum_k \zeta_{k,t+i}(x, \beta_t) \right| > \varepsilon_0 \right) \leq E \left( \sup_{\{\beta_i\} \in N^{n-\alpha} \varepsilon} \sup_{x \in X^+} n^{-1/2} \left( \sum_k \zeta_{k,t+i}(x, \beta_t) \right)^2 \right) = E \left( \sup_{\{\beta_i\} \in N^{n-\alpha} \varepsilon} \sup_{x \in X^+} n^{-1} \sum_k \zeta_{k,t+i}^2(x, \beta_t) \right) \\
+ E \left( \sup_{\{\beta_i, \beta_{i+1}\} \in N^{n-\alpha} \varepsilon} \sup_{x \in X^+} \sum_j n^{-1} \sum_{t=1}^{T-|j|} \zeta_{k,t+i}(x, \beta_t) \zeta_{k,t+i+j}(x, \beta_{t+j}) \right) \leq E \left( \sup_{\{\beta_i\} \in N^{n-\alpha} \varepsilon} \sup_{x \in X^+} n^{-1} \sum_k \left( \zeta_{k,t+i}(x, \beta_t) \right)^2 \right) \\
+ \sum_j n^{-1} \sum_{t=1}^{T-|j|} E \left[ \sup_{\{\beta_i, \beta_{i+1}\} \in N^{n-\alpha} \varepsilon} \sup_{x \in X^+} \zeta_{k,t+i}(x, \beta_t) \zeta_{k,t+i+j}(x, \beta_{t+j}) \right] \right) \right) \right). \tag{A.12}
\]

For part (a), substituting the results of Lemma A.3 into (A.12), the r.h.s. of (A.12) is less than or equal to

\[
\bar{C}(n^{-\alpha}\varepsilon) + \sum_j (1 - |j|/n)\alpha \alpha(j)(n^{-\alpha}\varepsilon)^2 \\
\leq \bar{C} n^{-\alpha}\varepsilon \left\{ 1 + 2 \sum_{j=1}^{n-1} \alpha(j) \right\} \\
\leq C n^{-\alpha}\varepsilon, \quad \text{say,} \tag{A.13}
\]

provided \(0 < n^{-\alpha}\varepsilon < 1\). Where \(0 < C \equiv \left\{ 1 + 2 \sum_{j=0}^{\infty} \alpha(j) \right\} \bar{C} < \infty\). Thus we can choose \(T_1\) and \(\varepsilon\) such that for all \(T > T_1 > T_0, \varepsilon < (\delta \varepsilon_0)^{n/2}/2C\) and \(0 < n^{-\alpha}\varepsilon < 1\), the result follows.

Similarly, for part (b), (A.13) holds by Lemma A.3 if we replace \(\alpha(j)\) by \(\alpha(j)^{\delta/(2+\delta)}\). In this case,

\[
0 < C \equiv \left\{ 1 + 2 \sum_{j=0}^{\infty} \alpha(j)^{\delta/(2+\delta)} \right\} \bar{C} < \infty \quad \text{by Assumption A.1* (see Eq. (14.6) in Davidson, 1994).}
\]

Then the result follows analogously.

**Lemma A.5.** (a) Suppose Assumptions A.1-A.4 hold. Then, we have for \(k = 1, \ldots, l\),

\[
\sup_{x \in X^+} \left| \xi_{k2}(x) - \sqrt{n} \Delta_k(x) B_k H_{k,n} + \sqrt{n} \Delta_{10}(x) B_{10} H_{1,n} \right| = o_p(1), \quad \tag{A.14}
\]

\[
\sup_{x \in X^-} \left| \xi_{k2}(x) - \sqrt{n} \Delta_k(x) B_k H_{k,n} + \sqrt{n} \Delta_{10}(x) B_{10} H_{1,n} \right| = o_p(1). \quad \tag{A.15}
\]

(b) Suppose Assumptions A.1*, A.2, A.3* and A.4 hold. Then, we have for \(k = 1, \ldots, l\),

\[
\sup_{x \in X^+} \left| \xi_{k2}(x) - \sqrt{n} \Delta_k(x) B_k H_{k,n} + \sqrt{n} \Delta_{10}(x) B_{10} H_{1,n} \right| = o_p(1), \quad \tag{A.16}
\]

\[
\sup_{x \in X^-} \left| \xi_{k2}(x) - \sqrt{n} \Delta_k(x) B_k H_{k,n} + \sqrt{n} \Delta_{10}(x) B_{10} H_{1,n} \right| = o_p(1). \quad \tag{A.17}
\]
Proof of Lemma A.5. We first prove part (a). Recall that \( \Delta_{k_0}(x) = (\partial F_k(x, \beta_{k_0})/\partial \beta) \text{sgn}(x) \) and 
\( \xi_{k_{21}}^\theta(x) = n^{-1/2} \sum_{t=1}^p \left[ F_k \left( x, \beta_{k,t} \right) - F_k(x, \beta_{k_0}) - F_1 \left( x, \beta_{1,t} \right) + F_1(x, \beta_{1_0}) \right] \text{sgn}(x) \), WLOG, we consider the case \( x \geq 0 \) and prove
\[
\sup_{x \in X^+} n^{-1/2} \sum_t \left( F_k \left( x, \beta_{k,t} \right) - F_k(x, \beta_{k_0}) \right) - \sqrt{n} \left( \frac{\partial F_k(x, \beta_{k_0})}{\partial \beta_k} \right) B_k \mathcal{H}_{k,n} = o_p(1). \tag{A.18}
\]
By Assumption A.3 (i) and the mean value theorem,
\[
n^{-1/2} \sum_t \left\{ F_k \left( x, \beta_{k,t} \right) - F_k(x, \beta_{k_0}) \right\} = n^{-1/2} \sum_t \left( \frac{\partial F_k(x, \beta_{k,t}(x))}{\partial \beta_k} \right) (\beta_{k,t} - \beta_{k_0}),
\]
where \( \beta_{k,t}(x) \) lies between \( \beta_{k,t} \) and \( \beta_{k_0} \). By Lemma A.1 (b), for all \( \alpha \in [0, 1/2] \) and all \( \varepsilon > 0 \), there exists \( \delta \), such that \( P(\sup_t \sup_{x \in X^+} n^\alpha \| \beta_{k,t}(x) - \beta_{k_0} \| \leq \varepsilon) < \delta/2 \) for sufficiently large \( n \). Let
\[
A_{1n} = \sup_{x \in X^+} \sup_{\{ \beta_k \} \in N_n(n^{-\alpha} \varepsilon)} \left\| \frac{\partial F_k(x, \beta_k)}{\partial \beta_k} - \frac{\partial F_k(x, \beta_{k_0})}{\partial \beta_k} \right\|.
\]
Then \( A_{1n} = O(n^{-\alpha}) \) by Assumption A.3(ii).
\[
A_{2n} \equiv \sup_{x \in X^+} \left\| n^{-1} \sum_t \left( \frac{\partial F_k(x, \beta_{k,t}(x))}{\partial \beta_k} - \frac{\partial F_k(x, \beta_{k_0})}{\partial \beta_k} \right) \right\|
\leq \sup_{x \in X^+} \sup_t \left\| \frac{\partial F_k(x, \beta_{k,t}(x))}{\partial \beta_k} - \frac{\partial F_k(x, \beta_{k_0})}{\partial \beta_k} \right\| = O_p(n^{-\alpha}).
\]
where the last equality holds because \( P(A_{2n} \leq A_{1n}) \to 1 \) as \( n \to \infty \) by construction. Now we have the desired result
\[
\sup_{x \in X^+} \left| n^{-1/2} \sum_t \left( F_k \left( x, \beta_{k,t} \right) - F_k(x, \beta_{k_0}) \right) - n^{1/2} \left( \frac{\partial F_k(x, \beta_{k_0})}{\partial \beta_k} \right) B_k \mathcal{H}_{k,n} \right|
= \sup_{x \in X^+} \left| n^{-1/2} \sum_t \left( \frac{\partial F_k(x, \beta_{k,t}(x))}{\partial \beta_k} \right) (\beta_{k,t} - \beta_{k_0}) - n^{1/2} \left( \frac{\partial F_k(x, \beta_{k_0})}{\partial \beta_k} \right) B_k \mathcal{H}_{k,n} \right|
\leq A_{2n} \sup_t \left| \sqrt{n} \left( \beta_{k,t} - \beta_{k_0} \right) \right| + \sup_{x \in X^+} \left| \frac{\partial F_k(x, \beta_{k_0})}{\partial \beta_k} \right| \left| n^{-1/2} \sum_t (\beta_{k,t} - \beta_{k_0}) - B_k \sqrt{n} \mathcal{H}_{k,n} \right|
= o_p(1) + o_p(1) = o_p(1)
\]
where the first \( o_p(1) \) follows from the fact that \( A_{2n} \sup_{t=1, \ldots, T} \left| \sqrt{n} \left( \beta_{k,t} - \beta_{k_0} \right) \right| = O_p(n^{-\alpha(1+\eta)/2}) = o_p(1) \) for all \( \alpha \in (1/2(1 + \eta), 1/2) \) by Lemma A.1(b), and the second \( o_p(1) \) holds by Assumption A.3(iii),
Lemma A.1(c) and the following argument

\[
\left\| n^{-1/2} \sum_{t=R}^{T} (\beta_{k,t} - \beta_{k0}) - B_k \sqrt{nH_{k,n}} \right\| = \left\| n^{-1/2} \sum_{t=R}^{T} B_k(t)H_k(t) - B_k n^{-1/2} \sum_{t=R}^{T} H_k(t) \right\| \\
= \left\| n^{-1/2} \sum_{t=R}^{T} (B_k(t) - B_k)H_k(t) \right\| \\
\leq \sup_{t} \| B_k(t) - B_k \| \sup_{t} n^{1/2} \| H_k(t) \| \\
= o_p(1)O_p(1) = o_p(1).
\]

The proof of part (b) is similar and thus omitted.

**Lemma A.6.** (a) Suppose Assumptions A.1-A.4 hold. Then, we have for \( k = 2, \ldots, l, \)

\[
\left( v_{k,n}^g(\cdot, \beta_{k0}) - v_{1,n}^g(\cdot, \beta_{1,0}) \right) \Rightarrow \left( \bar{g}_k(\cdot) \right)
\]

and except at zero, the sample paths of \( \bar{g}_k(\cdot) \) are uniformly continuous with respect to a pseudometric \( \rho_g \) on \( \mathcal{X} \) with probability one, where for \( x_1, x_2 \in \mathcal{X}^+ \) or \( x_1, x_2 \in \mathcal{X}^-, \)

\[
\rho_g(x_1, x_2) = \left\{ E \left[ (1(e_{1,t} \leq x_1) - 1(e_{k,t} \leq x_1)) - (1(e_{1,t} \leq x_2) - 1(e_{k,t} \leq x_2)) \right] \right\}^{1/2}.
\]

(b) Suppose Assumptions A.1*, A.2, A.3* and A.4 hold. Then, we have for \( k = 2, \ldots, l, \)

\[
\left( v_{k,n}^c(\cdot, \beta_{k0}) - v_{1,n}^c(\cdot, \beta_{10}) \right) \Rightarrow \left( \bar{c}_k(\cdot) \right)
\]

and except at zero, the sample paths of \( \bar{c}_k(\cdot) \) are uniformly continuous with respect to a pseudometric \( \rho_c \) on \( \mathcal{X} \) with probability one, where for \( x_1, x_2 \in \mathcal{X}^+ \) or \( x_1, x_2 \in \mathcal{X}^-, \)

\[
\rho_c(x_1, x_2) = \left\{ E \left[ \int_{-\infty}^{x_1} (1(e_{1,t} \leq s) - 1(e_{k,t} \leq s)) ds - \int_{-\infty}^{x_2} (1(e_{1,t} \leq s) - 1(e_{k,t} \leq s)) ds \right] \right\}^{1/r} 1(x_1 < 0, x_2 < 0)
\]

\[
+ \left\{ E \left[ \int_{x_1}^{\infty} (1(e_{1,t} > s) - 1(e_{k,t} > s)) ds - \int_{x_2}^{\infty} (1(e_{1,t} > s) - 1(e_{k,t} > s)) ds \right] \right\}^{1/r} 1(x_1 \geq 0, x_2 \geq 0).
\]

**Proof of Lemma A.6.** We first prove (a). By Theorem 10.2 of Pollard (1990), the results hold if we have (i) total boundedness of the pseudometric space \( (\mathcal{X}, \rho_g) \), (ii) stochastic equicontinuity of \( \left\{ v_{k,n}^g(\cdot, \beta_{k0}) - v_{1,n}^g(\cdot, \beta_{10}) : n \geq 1 \right\} \) and (iii) finite dimensional (fidi) convergence. The first two conditions follow from Lemma A.2. We now verify condition (iii), i.e., we need to show that \( (v_{k,n}^g(x_1, \beta_{k0}) - v_{1,n}^g(x_1, \beta_{10}), \ldots, v_{k,n}^g(x_J, \beta_{10}) - v_{1,n}^g(x_J, \beta_{k0}), \sqrt{nH_{k,n}}, \sqrt{nH_{1,n}})^T \) converges in distribution to \( (\bar{g}_k(x_1), \ldots, \bar{g}_k(x_J), v_{k0}^g, v_{10}^g)^T \) for all \( x_1, \ldots, x_J \in \mathcal{X}^+ \) and \( \forall J \geq 1. \) The central limit theorem (CLT) holds for \( \sqrt{nH_{k,n}} \) by Lemma 4.1 in West (1996). A CLT for bounded random variables under \( \alpha \)-mixing
conditions (see Hall and Heyde, 1980) hold for $v_{k,n}^g(x_j, \beta_{k0}) - v_{l,n}^g(x_j, \beta_{l0})$, $j = 1, ..., J$. Then one obtains the above weak convergence result by the Cramer-Wold device. This establishes part (a).

For part (b), we need to verify the fidi convergence again. Note that the moment condition of Hall and Heyde (1980, Corollary 5.1) holds since (WLOG), for $x > 0$,

$$E \int_x^\infty (1(e_{1,t} > s)ds - 1(e_{k,t} > s))ds \leq E|e_{1,t} - e_{k,t}|^{2+\delta} < \infty.$$ 

The mixing condition also holds since we have $\sum \alpha(j)^{\delta/(2+\delta)} \leq C \sum j^{-\delta/(2+\delta)} < \infty$ by Assumption A.1*

**Proof of Theorem 3.1**

WLOG, we consider the case $x \geq 0$. To prove part (a), note that

$$TG_n = \max_{k=2, \ldots, l} \sup_{x \in X^+} \sqrt{n}D_{k,n}^g(x) = \max_{k=2, \ldots, l} \sup_{x \in X^+} \{\xi_{k1}^g(x) + \xi_{k2}^g(x) + \xi_{k3}^g(x)\}.$$ 

Recall that $TG^+ = 0$ implies that the set $B_k^g$ is not empty and under the null, $\xi_{k3}^g(x) = n^{1/2}(F_k(x) - F_1(x))\text{sgn}(x) \rightarrow -\infty$ for all $x \not\in B_k^g$. Consequently,

$$TG_{k,n}^+ = \sup_{x \in X^+} \sqrt{n}D_{k,n}^g(x)$$

$$\Rightarrow \sup_{x \in B_k^g} [\tilde{g}_k(x) + \Delta k_0(x)'B_kv_k0 - \Delta 10(x)'B_1v_{10}]$$

by Lemmas A.4(a) through A.6(a). The result follows from the Continuous Mapping Theorem (CMT).

Suppose $TG^+ > 0$. In this case, the set $B_k^g$ is empty and hence $n^{-1/2}\xi_{k3}^g(x) < 0 \forall x \in X^+$, for some $k \in \{2, \ldots, l\}$. Then for such $k$, $D_{k,n}^g(x)$ will be dominated by the term $\xi_{k3}^g(x)$ which diverges to minus infinity for any $x \in X^+$ as required.

To prove part (b), note that

$$TC_n^+ = \max_{k=2, \ldots, l} \sup_{x \in X^+} D_{k,n}^g(x) = \min_{k=2, \ldots, l} \sup_{x \in X^+} \{\xi_{k1}^g(x) + \xi_{k2}^g(x) + \xi_{k3}^g(x)\}.$$ 

If $TC^+ = 0$, the set $B_k^g$ is not empty and under the null, $\xi_{k3}^g(x) \rightarrow -\infty$ for all $x \not\in B_k^g$. Consequently,

$$TC_{k,n}^+ = \sup_{x \in X^+} D_{k,n}^g(x)$$

$$\Rightarrow \sup_{x \in B_k^g} [\tilde{g}_k(x) + \Lambda k_0(x)'B_kv_k0 - \Lambda 10(x)'B_1v_{10}]$$

by Lemmas A.4(b) through A.6(b). Then the result follows from the CMT.

Next suppose $TC^+ < 0$. In this case, the set $B_k^g$ is empty and hence $n^{-1/2}\xi_{k3}^g(x) < 0 \forall x \in X^+$, for some $k \in \{2, \ldots, l\}$. Then for such $k$, $D_{k,n}^g(x)$ will be dominated by the term $\xi_{k3}^g(x)$ which diverges to minus infinity for any $x \in X^+$ as required. The conclusion thus follows.
Proof of Theorem 3.2

Adding and subtracting appropriately gives

\[
\sqrt{n}(G^*_k(x) - G_k(x)) = n^{-1/2} \sum_t \left[ f^g_{k,\theta(t)+\tau}(x, \hat{\beta}_{k,\theta(t)}) - f^g_{k,t+\tau}(x, \hat{\beta}_k) \right]
\]

\[
= n^{-1/2} \sum_t \left[ f^g_{k,\theta(t)+\tau}(x, \beta_k) - f^g_{k,t+\tau}(x, \beta_k) \right]
\]

\[
- n^{-1/2} \sum_t \left[ f^g_{k,t+\tau}(x, \hat{\beta}_k) - f^g_{k,t+\tau}(x, \beta_k) \right]
\]

\[
+ n^{-1/2} \sum_t \left[ f^g_{k,\theta(t)+\tau}(x, \hat{\beta}_{k,\theta(t)}) - f^g_{k,t+\tau}(x, \beta_k) \right]
\]

\[
\equiv \varsigma_{1,n}(x) - \varsigma_{2,n}(x) + \varsigma_{3,n}(x)
\]

Under Assumptions A.1-A.4 and A.6, Theorem 3.1 of Politis and Romano (1994b) applies to get \(\rho(L[\varsigma_{1,n}()][U_1, ..., U_{T+\tau}], L[G_{kn}()] - G_k()) \xrightarrow{L} 0\). And

\[
\varsigma_{2,n}(x) = n^{-1/2} \sum_t \left[ E f^g_{k,t+\tau}(x, \beta_k) | \beta_k = \beta_k \right] - E f^g_{k,t+\tau}(x, \beta_k)
\]

\[
+ n^{-1/2} \sum_t \left[ f^g_{k,t+\tau}(x, \hat{\beta}_k) - E f^g_{k,t+\tau}(x, \beta_k) | \beta_k = \beta_k \right] - f^g_{k,t+\tau}(x, \beta_k) + E f^g_{k,t+\tau}(x, \beta_k)
\]

\[
= o_p(1) + o_p(1) = o_p(1) \text{ uniformly in } x \in \mathcal{X}^+ \text{ or } x \in \mathcal{X}^-,
\]

where the second equality follows from Lemmas A.4(a) and A.5(a). The result follows if \(P[\sup_{x \in \mathcal{X}^+} \varsigma_{3,n}(x) = o_Q(1)] \rightarrow 1\) as \(n\) increases, where \(Q\) is the probability distribution induced by the stationary bootstrap conditional on the data \((U_1, ..., U_{T+\tau})\). Note that \(\varsigma_{3,n}(x) = \varsigma_{3,n}(x) - \varsigma_{3,n}(x)\), where \(\varsigma_{3,n}(x) = n^{-1/2} \sum_t \left[ 1 \left( e_{k,\theta(t)+\tau}(\hat{\beta}_{k,\theta(t)}) \leq x \right) - 1(e_{k,t+\tau} \leq x) \right] \), and \(\sup_{x \in \mathcal{X}^+} |\varsigma_{3,n}(x)| \leq \sup_{x} |\varsigma_{3,n}(x)| + \sup_{x} |\varsigma_{3,n}(x)|\).

By the Markov inequality it suffices to show \(E_Q[\sup_{x} \varsigma_{3,n}(x)] = o_p(1)\), where \(E_Q\) is the expectation induced by the probability measure \(Q\). Note that

\[
E_Q \left| \sup_{x \in \mathcal{X}^+} \varsigma_{3,n}(x) \right|
\]

\[
= \left| \sup_{x \in \mathcal{X}^+} n^{-1/2} \sum_t \left[ 1 \left( e_{k,t+\tau}(\hat{\beta}_{k,t}) \leq x \right) - 1(e_{k,t+\tau} \leq x) \right] \right|
\]

\[
\leq n^{-1/2} \sum_t \left| \sup_{x \in \mathcal{X}^+} \left[ 1 \left( e_{k,t+\tau}(\hat{\beta}_{k,t}) \leq x \right) - 1(e_{k,t+\tau} \leq x) \right] \right|
\]

\[
\leq n^{-1/2} \sum_t \sup_{x \in \mathcal{X}^+} \left| e_{k,t+\tau} - x \right| \leq m_k \left( Z_{k,t+\tau}, \hat{\beta}_{k,t} \right) - m_k(Z_{k,t+\tau}, \beta_k)
\]

\[
\equiv \varsigma_n
\]

It suffices to show \(E[\varsigma_n] = o(1)\) by the Markov inequality and the nonnegativity of \(\varsigma_n\). Denote the \(j\)th elements of \(\hat{\beta}_{k,t}\) and \(\beta_k\) as \(\hat{\beta}_{k,t}^{(j)}\) and \(\beta_k^{(j)}\) respectively. By Assumption A.6, for all \(j\),
\[ \sup_j |\gamma_{k,t}^{(j)} - \gamma_{k,0}^{(j)}| \leq R^{-1/2} \sigma_j (\log \log R \sigma_j)^{1/2} \text{ a.s., where } \sigma_j \text{ is the } j\text{th diagonal element of } \Sigma_k. \] The assumption \((n/R)(\log \log R) = o(1)\) trivially ensures \(\max_j \sup_t |n^{1/2} \left( \frac{\gamma_{k,t}^{(j)} - \gamma_{k,0}^{(j)}}{\sigma_{k,t}^{(j)}} \right) - \sigma_{k,0}^{(j)}| = o_{a.s.}(1).\) Fix \(\epsilon_0, \delta > 0.\)

Then for all \(\epsilon > 0,\) there exists \(T_0\) such that for all \(T > T_0, \) \(P \left[ \max_j \sup_t n^{1/2} \left( \frac{\gamma_{k,t}^{(j)} - \gamma_{k,0}^{(j)}}{\sigma_{k,t}^{(j)}} \right) > \epsilon \right] < \frac{\delta}{2}.\)

It is useful to note that for all \(t \in [0, T],\) \(E_\beta \left[ f \left( \frac{\gamma_{k,t}^{(j)} - \gamma_{k,0}^{(j)}}{\sigma_{k,t}^{(j)}} \right) \right] = \frac{n^{1/2} \left( \frac{\gamma_{k,t}^{(j)} - \gamma_{k,0}^{(j)}}{\sigma_{k,t}^{(j)}} \right)}{\sigma_{k,0}^{(j)}} + \frac{n^{1/2} \left( \frac{\gamma_{k,0}^{(j)}}{\sigma_{k,0}^{(j)}} \right)}{\sigma_{k,0}^{(j)}}.\)

**Proof of Theorem 4.1**

WLOG, we consider the case \(x \geq 0.\) Recall that

\[ TG_n^+ = \max_{k=2, \ldots, j} \sup_{x \in X^+} \sqrt{n} D_{k,n}^g(x) = \max_{k=2, \ldots, j} \sup_{x \in X^+} \{ \xi_{k1}^g(x) + \xi_{k2}^g(x) + \xi_{k3}^g(x) \}. \]
If $TG^+ > 0$, Lemmas A.4(a)-A.6(a) continue to hold so that $\xi_{k1}^g(x) = O_p(1)$ uniformly in $x \in X^+$, and $\xi_{k2}^g(x) = o_p(1)$ uniformly in $x \in X^+$. For each $k \in \{2, \ldots, l\}$, $\xi_{k3}^g(x) = n^{1/2} (F_k(x) - F_1(x)) \text{sgn}(x) \to \infty$ for some $x \in X^+$. Consequently, $TG_n^+ \overset{P}{\to} \infty$ as $T \to \infty$ and $n^{-1/2}TG_n^+ \overset{P}{\to} TG^+ > 0$.

Now, from Corollary 3.3,

$$\rho\left[ \max_{k=2,\ldots,l} \sup_{x \in X^+} \sqrt{n} (G_{k,n}(x) - G_{k,n}(x)) ; U_1, \ldots, U_{T+\tau} \right] \rho\left[ \max_{k=2,\ldots,l} \sup_{x \in X^+} \sqrt{n} (G_{k,n}(x) - G_{k}(x)) \right] \overset{P}{\to} 0,$$

which implies $q_{G,n,S_n}^+(1-\alpha) = \tilde{q}_{n,S_n}^+(1-\alpha) + o_p(1)$, where $\tilde{q}_{n,S_n}^+(1-\alpha)$ is the $(1-\alpha)$-th sample quantile of $\tilde{TG}^+ = \max_{k=2,\ldots,l} \sup_{x \in X^+} \sqrt{n} (G_{k,n}(x) - G_{k}(x))$.

$$\tilde{TG}_n^+ = O_p(1) \text{ and it has the limiting distribution (3.3) by the proof of Theorem 3.1 (a) and } \tilde{TG}_2,n^+ = o_p(1) \text{ by the proof of Theorem 3.2. Consequently, } \tilde{q}_{n,S_n}^+(1-\alpha) \overset{P}{\to} q^+(1-\alpha) \text{ and }$$

$$P\left( TG_n^+ > q_{n,S_n}^+(1-\alpha) \right) = P\left( TG_n^+ > q^+(1-\alpha) + o_p(1) \right)$$

$$= P\left( n^{-1/2}TG_n^+ > n^{-1/2}q^+(1-\alpha) \right) + o_p(1)$$

$$= P\left( TG^+ > n^{-1/2}q^+(1-\alpha) \right) + o_p(1)$$

$$\to 1.$$

**Proof of Theorem 4.2.**

The proof is similar to that of Theorem 3.1. Consider Lemmas A.1-A.6 with $v_{k,n}^\beta(x, \beta_k)$ now defined by

$$v_{k,n}^\beta(x, \beta_k) = n^{-1/2} \sum_t [1(\epsilon_{k,t+\tau}(\beta_k) \leq x) - F_k(x, \beta_k)] \text{sgn}(x) \text{ for } k = 1, \ldots, l.$$

Then by contiguity, the result of Lemmas A.4(a) holds under the local alternatives. Lemma A.5(a) now
changes to \( \sup_{x \in X^+} |\xi_{k,t}^{q}(x) - \sqrt{n} \Delta_{k,0}(x) B_k \overline{P}_{k,n} + \sqrt{n} \Delta_{1,0}(x) B_1 \overline{P}_{1,n}| = o_p(1) \), because WLOG

\[
\begin{align*}
\sup_{x \in X^+} & \left[ n^{-1/2} \sum_{t} \left( \frac{\partial F_{k,n}(x, \beta_{kt})}{\partial \beta^q_k} - F_k(x, \beta_{k0}) - \sqrt{n} \Delta_{k,0}(x) B_k \overline{P}_{k,n} \right) \right] \\
= & \sup_{x \in X^+} \left[ n^{-1/2} \sum_{t} \left( \frac{\partial F_{k,n}(x, \beta_{k,t}(x))}{\partial \beta^q_k} - \frac{\partial F_k(x, \beta_{k0})}{\partial \beta^q_k} \right) \right] \\
\leq & \sup_{x \in X^+} \left[ n^{-1/2} \sum_{t} \left( \frac{\partial F_{k,n}(x, \beta_{k,t}(x))}{\partial \beta^q_k} - \frac{\partial F_k(x, \beta_{k0})}{\partial \beta^q_k} \right) \right] \\
+ & \sup_{x \in X^+} \left| \Delta_{k,0}(x) \right| \left( n^{-1/2} \sum_{t} \left( \beta_{k,t} - \beta_{k0} \right) - B_k \sqrt{n} \overline{P}_{k,n} \right) \\
= & o_p(1) + o_p(1) = o_p(1).
\end{align*}
\]

Therefore, it suffices to show that Lemma A.6 (a) holds under the local alternatives. This follows by a modification of the proof of Lemma A.6(a) and using the CLT of Herrndorf (1984) for \( \alpha \)-mixing arrays to verify the third convergence condition of Theorem 10.2 of Pollard (1990).

**Proof of Corollary 4.3**

By contiguity, \( q_{n,S_n}^{G+}(1 - \alpha) \xrightarrow{P} q^{G+}(1 - \alpha) \) under the local alternatives. The result now follows immediately from Theorem 4.2.

**Proof of Theorem 5.4**

To prove Theorem 5.4, we need the following two lemmas.

**Lemma HA.1** (a) Suppose Assumption HA.1 holds. Then, for each \( \varepsilon > 0 \), there exists \( \delta > 0 \) such that for all \( x, \hat{x} \in X^+ \) or \( x, \hat{x} \in X^- \),

\[
\lim_{T \to \infty} \left\| \sup_{\rho_{k,n}(x, \hat{x}) < \delta} \rho_{k,n}^{0q}(x) - \rho_{k,n}^{0q}(\hat{x}) \right\|_q < \varepsilon, \quad (A.19)
\]

where

\[
\rho_{k,n}^{0q}(x, \hat{x}) = \left\{ E[1(e_{k,t+\tau} < x) - 1(e_{k,t+\tau} \leq \hat{x})]^2 \right\}^{1/2}.
\]

(b) Suppose Assumption HA.1*B holds. Then, for each \( \varepsilon > 0 \), there exists \( \delta > 0 \) such that for all \( x, \hat{x} \in X^+ \) or \( x, \hat{x} \in X^- \),

\[
\lim_{T \to \infty} \left\| \sup_{\rho_{k,n}(x, \hat{x}) < \delta} \rho_{k,n}^{0h}(x) - \rho_{k,n}^{0h}(\hat{x}) \right\|_q < \varepsilon, \quad (A.21)
\]

where

\[
\rho_{k,n}^{0h}(x, \hat{x}) = \left\{ E \left[ \int_{-\infty}^{x} 1(e_{k,t+\tau} \leq s)ds - \int_{-\infty}^{\hat{x}} 1(e_{k,t+\tau} \leq s)ds \right]^{r/2} 1(x < 0, \hat{x} < 0) \right. \\
+ \left. E \left[ \int_{x}^{\infty} 1(e_{k,t+\tau} > s)ds - \int_{\hat{x}}^{\infty} 1(e_{k,t+\tau} > s)ds \right]^{r/2} 1(x \geq 0, \hat{x} \geq 0) \right\}.
\]

(A.22)
Proof of Lemma HA.1  Assumptions HA.4 and HA.1 (i) (resp. HA.1* (i)) imply that \( \{e_{k,t+\tau} : t \geq R \} \) is an \( \alpha \)--mixing sequence with mixing coefficients \( \alpha(l) = O(l^{-C_0}) \), where \( C_0 \) is as defined in HA.1 (resp. HA.1*). Note that Theorem 2.2 in Andrews and Pollard (1994) and Theorem 3 in Hansen (1996) do not require any stationarity assumption, the proof is analogous to that of Lemma A.2. For example, for part (b), Eq. (12) of Hansen (1996) is satisfied with our mixing coefficient \( C_0 = 1/q - 1/r \), Eq. (12) is true by Assumption HA.1 (ii) and Equation (13) is satisfied with the dominating function \( b = 1 \). Then theorem 3 in Hansen (1996) follows by taking \( a = 1 \) and \( \lambda = 1 \).

Lemma HA.2. (a) Suppose Assumptions HA.1* and HA.4 hold. Then, we have for \( k = 2, \ldots, l \),

\[
v_{k,n}(\cdot) - v_{1,n}(\cdot) \Rightarrow \tilde{h}_{g}k(\cdot)
\]

and except at zero, the sample paths of \( \tilde{h}_{g}k(\cdot) \) are uniformly continuous with respect to a pseudometric \( \rho_{hg} \) on \( \mathcal{X} \) with probability one, where for \( x_1, x_2 \in \mathcal{X}^+ \) or \( x_1, x_2 \in \mathcal{X}^- \),

\[
\rho_{hg}(x_1, x_2) = \left\{ E\left[(1(e_{1,t+\tau} \leq x_1) - 1(e_{k,t+\tau} \leq x_1)) - (1(e_{1,t+\tau} \leq x_2) - 1(e_{k,t+\tau} \leq x_2))\right]^2\right\}^{1/2}.
\]

(b) Suppose Assumptions A.1*, A.2, A.3* and A.4 hold. Then, we have for \( k = 2, \ldots, l \),

\[
v_{k,n}(\cdot) - v_{1,n}(\cdot) \Rightarrow \tilde{h}_{c}k(\cdot)
\]

and except at zero, the sample paths of \( \tilde{h}_{c}k(\cdot) \) are uniformly continuous with respect to a pseudometric \( \rho_{hc} \) on \( \mathcal{X} \) with probability one, where for \( x_1, x_2 \in \mathcal{X}^+ \) or \( x_1, x_2 \in \mathcal{X}^- \),

\[
\rho_{hc}(x_1, x_2) = \left\{ E\left[\int_{x_1}^{x_2} (1(e_{1,t+\tau} \leq s) - 1(e_{k,t+\tau} \leq s))ds - \int_{-\infty}^{x_1} (1(e_{1,t+\tau} \leq s) - 1(e_{k,t+\tau} \leq s))ds\right]^{1/r}
1(x_1 < 0, x_2 < 0)
\right. \\
\left. + E\left[\int_{x_1}^{\infty} (1(e_{1,t+\tau} > s) - 1(e_{k,t+\tau} > s))ds - \int_{x_2}^{\infty} (1(e_{1,t+\tau} > s) - 1(e_{k,t+\tau} > s))ds\right]^{1/r}
1(x_1 \geq 0, x_2 \geq 0)\right\}^{1/r}.
\]

Proof of Lemma HA.2. The proof is analogous to that of Lemma A.6. The total boundedness of the pseudometric space \( (\mathcal{X}, \rho_i), i = hg \) and \( hc \), and the stochastic equicontinuity of \( \left\{ v_{i,n}(\cdot) - v_{1,n}(\cdot) : n \geq 1 \right\}, i = hg \) and \( hc \) follow from Lemma HA.1. The finite dimensional convergence follows from Hall and Heyde (1980). Then the result follows from Theorem 10.2 of Pollard (1990).

Proof of Theorem 5.4

The theorem follows from Lemmas HA.1 and HA.2 and the CMT.

*Notes: See Sections 3 and 6 for complete details. Size Experiments: DGP1 and DGP4. Power Experiments: DGP2, DGP3, DGP5, DGP6. Entries are rejection frequencies based on 1000 Monte Carlo replications. The number of bootstrap resamples is 300 and $S_n$ is the bootstrap smoothing parameter. Nominal test size is 10%.
