-

"... Every year six billion pounds of fruits and vegetables go to waste on farms across the U.S. just for looking a little different from other produce..."

- Reilly Brock, Blogger, Imperfect Produce, Aug. 2015

## That doesn't make sense.

.∃ >

#### Food Loss / Waste

- Scale of food waste problem huge
  - \$165 billion in value (Buzby et al. 2014)
  - 25% of fresh water (Hall et al. 2009)
  - 18% of volume in landfills (EPA 2016)
  - 300 million bbls of oil (Hall et al. 2009)
- Source of problem
  - Forecasting errors at each point in supply chain
  - Agents have no incentive to manage waste
- Sharing economy
  - Collaborative peer-to-peer mutualization systems (CPMS)
  - Uber, AirBnB, etc.
  - Create markets for under-utilized assets
  - Asset in this case is farmer's land
  - Botsman and Rogers (2010); Botsman (2013)

#### Growth of Imperfect Produce

. . . . . .

-

### How do CPMSs Work?

- Most CPMSs are two-sided platforms
  - Demand for service from user
  - Eg. The Uber-rider
  - Demand for distribution by asset-owner
  - Eg. The car-owner
  - The CPMS is the platform that connects the two
- All retailers are two-sided markets
  - Demand for goods by customers
  - Demand for shelf-space by suppliers
  - Richards and Hamilton (2013)
- Positive network externalities
  - Demand from customers rises in number of suppliers
  - Demand from suppliers rises in number of customers
  - Viability determined by strength of network effects
- If we can get this to work...

#### What We Do

- Model of two-sided demand for ugly produce
  - Consumer demand for "boxes"
  - Nested model of platform choice and items
- Model of supplier demand for distribution
  - Supply conditional on demand strength
  - Equilibrium model of pricing and variety on offer
- Estimate with data from CPMS in California
  - Imperfect Produce, Inc.
  - Sources fresh produce below retail grade
  - Sells boxes of produce on subscription
- Simulate changes in item prices
  - Find that 25% rise in price leads to 60% rise in demand
- Market-level impacts
  - CPMS diverts demand from traditional channels
  - Makes more complete use of land commited to produce

# Empirical Model

Image: Image:

.∃ >

#### Background

- Theory of network economics well-understood
  - Armstrong (2006)
  - Rochet and Tirole (2003, 2006)
  - Benefit to buyers rises in the number of ...
    - Other users
    - Software titles
    - Entries in yellow-pages, etc.
  - Virtuous cycle in which supply creates demand
- Empirical examples from technology
  - Computer hardware / software (Nair, Chintagunta, Dube 2004)
  - Video games (Clements and Ohashi 2005)
  - Intermediation systems (Caillaud and Jullien 2003)
  - Yellow pages (Rysman 2004; Kaiser and Wright 2006)
  - Many others
- We are the first to consider market for surplus food

### Surplus Food?

- Consumers demand variety
  - Draganska and Jain (2005)
  - Richards and Hamilton (2015)
  - Particularly true online (Brynjolfsson and Simester 2011)
  - Retail long-tail argument
- Suppliers demand distribution
  - Slotting fees paid by food manufacturers
  - Promotional allowances, pay-to-stay fees
  - Scan-based trading another example
  - There is a "price" for shelf-space
- Retail distribution is two-sided
- Optimal price and variety depends on:
  - Consumer preference for variety
  - Firm profit from distribution

- General definition of sharing economy
  - Botsman (2013)
  - What is a "sharing economy" firm?
  - Entity that facilitates the trade of underutilized products or services
- How it works
  - Suppliers enter item / volume on IP app
  - Products that do not make retail grade or over-contract
  - Buyers set up subscription for box
  - Boxes are S,M, or L and fruit or veg
  - Boxes are delivered by IP per schedule
  - IP picks up, assembles, and delivers
- Number of suppliers and items varies by:
  - Season
  - Category

### Overview of Model

#### • Structural model of surplus food

- Estimate demand from buyers
- Estimate supply from farmers
- Equilibrium model of item provision
- Simulate equilibrium for policy analysis
- Demand model
  - Household-level model of item-purchase
  - Nested model of:
    - Probability of purchase
    - Number of items purchased
  - Product is total number of items purchased
- Supply model
  - Assume Bertrand-Nash rivalry in price and variety
  - Estimate conditional on demand parameters
- Account for endogeneity in each part

#### Demand: Order Probability

• CES utility:

$$U_i(q_{i1}, q_{i2}, ...q_{iN}, z_i) = \left(\sum_{j=1}^N q_{ij}^{ heta}
ight)^{\sigma} + z_i,$$

• Where:

- $q_{ij}$  = quantity of item type j by household i
- $z_i =$  quantity of numeraire good
- Random indirect utility function:

$$V_i(p, N, y_i) = (1 - \sigma heta)(\sigma heta)^{rac{\sigma heta}{1 - \sigma heta}} N^{rac{\sigma(1 - heta)}{1 - \sigma heta}} p^{rac{\sigma heta}{\sigma heta - 1}} + y_i + arepsilon_i,$$

Where:

- CES price index is  $p = N_j^{\frac{\theta-1}{\theta}} p_j$  with symmetry
- For number of items  $N_j$  in box-type j.

- Assume  $\varepsilon_i$  are Type I Extreme Value distributed
- Probability *i* buys in week *t* is:

$$P_{it} = \Pr(V_{it} > V_{it}^* + \varepsilon_{it}) = rac{\exp(V_{it})}{(1 + \exp(V_{it}))}.$$

- Empirical model includes:
  - $\mathbf{x}_i$  = vector of household attributes (*CR*<sub>*it*</sub>, *ITT*<sub>*it*</sub>, etc)
  - $z_j$  = vector of box attributes (*SM<sub>j</sub>*, *PROM<sub>j</sub>*, *ORG<sub>j</sub>*, etc)
- Account for unobserved heterogeneity:

$$\sigma_i = \sigma_0 + \sigma_1 v_1, \ v_1 \tilde{\ } N(0,1) \theta_i = \theta_0 + \theta_1 v_2, \ v_2 \tilde{\ } N(0,1),$$

#### Demand: Number Purchased

Number purchased is an integer variable

• Poisson order-quantity model:

$$P(Q_{ijt} = q_{ijt} | Q_{ijt} > 0) = \frac{\exp(-\lambda_i)(\lambda_i)^{q_{ijt}}}{(1 - \exp(-\lambda_i))q_{ijt}!},$$

Where:

- $q_{ijt} =$  number of items by *i* on *t* in box *j*,
- $\lambda_i$  = Poisson distribution parameter with:

$$\lambda_i = \exp(\phi_{i0} + \phi_p p + \phi_N N + \sum_{k=1}^{K} \phi_k x_k)$$

- for  $x_k$  box-attribute variables above.
- Number purchased expected to:
  - Fall in price index p,
  - Rise in variety index N
  - $\phi_{\it N}=$  key love-of-variety parameter
- Test against Negative Binomial alternative.

• Platform profit expression:

$$\Pi_t = E[Q_t](p_t - r_t - w_t) - v(N_t),$$

- Where:
  - $E[Q_t] = expected number of items sold,$
  - $p_t = \text{price index},$
  - $r_t = \text{constant marginal cost of selling},$
  - $w_t =$  wholesale price of ugly produce,
  - $v(N_t) = \text{cost of variety: } v_N > 0.$
  - Cost of variety first-order TSE:  $v(N_t) = \gamma_0 N_t + (1/2)\gamma_1 N_t^2$
- Optimal platform price:

$$\mathbf{p} = \mathbf{r} + \mathbf{w} - \psi E[\mathbf{Q}_p]^{-1}E[\mathbf{Q}],$$

• Where:  $\mathbf{Q}_{p} = \text{matrix of demand price-derivatives.}$ 

## Supply: Variety

• First-order conditions in variety:

$$\boldsymbol{\nu}_N = -\boldsymbol{E}[\mathbf{Q}_N]\boldsymbol{E}[\mathbf{Q}_p]^{-1}\boldsymbol{E}[\mathbf{Q}],$$

#### Where:

- $\mathbf{Q}_{N} = matrix$  of demand variety-derivatives
- Marginal cost of variety:  $oldsymbol{
  u}_{N}=\gamma_{0}+\gamma_{1}oldsymbol{N}$
- Optimal variety expression:

$$\mathbf{N}=- au_{1}E[\mathbf{Q}]_{N}E[\mathbf{Q}]_{p}^{-1}E[\mathbf{Q}]- au_{0}$$
,

• Retailing cost:

$$r_{jt} = \delta_0 + \sum_{l=1}^L \delta_l v_l$$

Where:

- $v_l = \text{input-price indices (retail wages, fuel, etc.)}$
- Estimate pricing, variety, retailing cost together
- Account for endogeneity using control function method.

## Data

・ロト ・ 日 ト ・ ヨ ト ・ ヨ ト

- Imperfect Produce, Inc.
  - Started by Ben Curtis, Ben Chesler, Ron Clark in 2015
  - Now have over 7,500 subscription-customers
  - Ben<sup>2</sup> from The Recovery Network
- Transactional data from Jan 2016 Feb 2017.
  - ID for purchaser, date of purchase
  - Price paid for box, box contents
  - Promotional activity
  - Wholesale price paid by IP
  - No demographics for households
- Supply data
  - Invoice data for purchases
  - But, no consistent volume measure
  - ID numbers for suppliers allows N calculation

Table 1. Data Summary

| Variable          | Units     | Mean    | Std. Dev. | Min. | Max.   | Ν      |
|-------------------|-----------|---------|-----------|------|--------|--------|
| Number of Items   | #         | 46.3801 | 14.5647   | 29   | 83     | 201836 |
| Box Size          | #         | 7.5409  | 3.9272    | 4    | 12     | 201836 |
| Order Dollars     | \$        | 20.3375 | 11.1023   | 6    | 450    | 201836 |
| Order Items       | #         | 13.5346 | 7.6526    | 4    | 381    | 201836 |
| Promotion Dollars | \$        | 0.2719  | 2.3352    | 0    | 140.12 | 201836 |
| Item Price        | \$ / Item | 1.5710  | 0.2727    | 0.38 | 11.18  | 201836 |
| Organic           | %         | 26.4185 | 44.0899   | 0    | 100    | 201836 |
| Fruit             | %         | 1.9283  | 13.7518   | 0    | 100    | 201836 |
| Vegetable         | %         | 2.2389  | 14.7947   | 0    | 100    | 201836 |
| Small             | %         | 24.5338 | 43.0288   | 0    | 100    | 201836 |
| Medium            | %         | 21.2296 | 40.8934   | 0    | 100    | 201836 |
| Large             | %         | 4.4452  | 20.6097   | 0    | 100    | 201836 |

Note: Data from Imperfect Produce, LLC.

Table 6. Policy Simulations: Subsidizing Ugly Produce

Note: t-ratio compares subsidy to 0% (base case).

# Conclusions

Image: A image: A

3 ×

• Imperfect Produce subject to indirect network effects

- Equilibrium price rises in network size
- Network size rises in price
- Simulations show
  - Strength of network effect affects price / network
  - Subsidizing surplus food strengthens price / network
  - Isomorphic to tax on discarded food
- We rock!
