#### Abstract

This paper considers tests and confidence sets (CS's) concerning the coefficient on the endogenous variable in the linear IV regression model with homoskedastic normal errors and one right-hand side endogenous variable. The paper derives a finite-sample lower bound function for the probability that a CS constructed using a two-sided invariant similar test has infinite length and shows numerically that the conditional likelihood ratio (CLR) CS of Moreira (2003) is not always "very close," say .005 or less, to this lower bound function. This implies that the CLR test is not always very close to the two-sided asymptotically-efficient (AE) power envelope for invariant similar tests of Andrews, Moreira, and Stock (2006) (AMS).

On the other hand, the paper establishes the finite-sample optimality of the CLR test when the correlation between the structural and reduced-form errors, or between the two reduced-form errors, goes to 1 or -1 and other parameters are held constant, where optimality means achievement of the two-sided AE power envelope of AMS. These results cover the full range of (non-zero) IV strength.

The paper investigates in detail scenarios in which the CLR test is not on the two-sided AE power envelope of AMS. Also, theory and numerical results indicate that the CLR test is close to having greatest average power, where the average is over a grid of concentration parameter values and over pairs alternative hypothesis values of the parameter of interest, uniformly over pairs of alternative hypothesis values and uniformly over the correlation between the structural and reduced-form errors. Here, "close" means .015 or less for $k \leq 20$, where $k$ denotes the number of IV's, and .025 or less for $0<k \leq 40$.

The paper concludes that, although the CLR test is not always very close to the two-sided AE power envelope of AMS, CLR tests and CS's have very good overall properties.

Keywords: Conditional likelihood ratio test, confidence interval, infinite length, linear instrumental variables, optimal test, weighted average power, similar test.

JEL Classification Numbers: C12, C36.

## 1 Introduction

The linear instrumental variables (IV) regression model is one of the most widely used models in economics. It has been widely studied and considerable effort has been made to develop good estimation and inference methods for it. In particular, following the recognition that standard two stage least squares $t$ tests and confidence sets (CS's) can perform quite poorly under weak IV's (see Dufour (1997), Staiger and Stock (1997), and references therein), inference procedures that are robust to weak IV's have been developed, e.g., see Kleibergen (2002) and Moreira (2003, 2009). The focus has been on models with one right-hand side (rhs) endogenous variable, because this arises most frequently in applications, and on over-identified models, because Anderson and Rubin (1949) (AR) tests and CS's are robust to weak IV's and perform very well in exactly-identified models.

Andrews, Moreira, and Stock (2006) (AMS) develop a finite-sample two-sided AE power envelope for invariant similar tests concerning the coefficient on the rhs endogenous variable in the linear IV model under homoskedastic normal errors and known reduced-form variance matrix. They show via numerical simulations that the conditional likelihood ratio (CLR) test of Moreira (2003) has power that is essentially (i.e., up to simulation error) on the power envelope. Chernozhukov, Hansen, and Jansson (2009) (CHJ) show that this power envelope also applies to non-invariant tests provided the envelope is for power averaged over certain direction vectors in a unit sphere. CHJ also shows that the invariant similar tests that generate the two-sided AE power envelope are $\alpha$-admissible and $d$-admissible. Mikusheva (2010) provides approximate optimality results for CLR-based CS's that utilize the testing results in AMS. Chamberlain (2007), Andrews, Moreira, and Stock (2008), and Hillier (2009) provide related results.

It is shown in Dufour (1997) that any CS with correct size $1-\alpha$ must have positive probability of having infinite length at every point in the parameter space. The AR and CLR CS's have this property. In fact, simulation results show that in some over-identified contexts the AR CS has a lower probability of having an infinite length than the CLR CS does. For example, consider a model with one rhs endogenous variable, $k$ IV's, a concentration parameter $\lambda_{v}$ (which is a measure of the strength of the IV's), homoskedastic normal errors, a correlation $\rho_{u v}$ between the structuralequation error and the reduced-form error (for the first-stage equation) equal to zero, and no covariates. When $\left(k, \lambda_{v}\right)$ equals $(2,7),(5,10),(10,15),(20,15)$, and $(40,20)$, the differences between the probabilities that the $95 \%$ CLR and AR CS's have infinite length are $.013, .027, .037, .043$, and .049 , respectively ${ }^{1}$ In fact, one obtains positive differences for all combinations of ( $k, \lambda_{v}$ ) for $k=2,5,10,20,40$ and $\lambda_{v}=1,5,10,15,20$. Hence, in these over-identified scenarios the AR CS

[^1]outperforms the CLR CS in terms of its infinite-length behavior, which is an important property for CS's. Similarly, one obtains positive (but smaller) differences also when $\rho_{u v}=.3$ for the same range of ( $k, \lambda_{v}$ ) values. On the other hand, for $\rho_{u v}=.5, .7$, and .9 , the differences are negative over the same range of $\left(k, \lambda_{v}\right)$ values.

The AR and CLR CS's are based on inverting AR and CLR tests that fall into the class of invariant similar tests considered in AMS. Hence, the simulation results for $\rho_{u v}=.0$ and .3 raise the question: how can these results be reconciled with the near optimal CLR test and CS results described above? In this paper, we answer this question and related questions concerning the optimality of the CLR test and CS.

The contributions of the paper are as follows. First, the paper shows that the probability that an invariant similar CS has infinite length for a fixed true parameter value $\beta_{*}$ equals one minus the power against $\beta_{*}$ of the test used to construct the CS as the null value $\beta_{0}$ goes to $\infty$ or $-\infty$. This leads to explicit formulae for the probabilities that the AR and CLR CS's have infinite length.

Second, the paper determines a finite-sample lower bound function on the probabilities that a CS has infinite length for CS's based on invariant similar tests. This lower bound is obtained by using the first result and finding the limit of the power bound in AMS as the null value $\beta_{0}$ goes to $\infty$ or $-\infty$. The lower bound function is found to be very simple. It is a function only of $\left|\rho_{u v}\right|$, $\lambda_{v}$, and $k$. These results allow one to compare the probabilities that the AR and CLR CS's have infinite length with the lower bound.

Third, simulation results show that the AR and CLR CS's are not always close to the lower bound. This is not surprising for the AR CS, but it is surprising for the CLR CS in light of the AMS results. The probabilities that the CLR CS has infinite length are found to be off the lower bound function by a magnitude that is decreasing in $\left|\rho_{u v}\right|$, increasing in $k$, and are maximized over $\lambda_{v}$ at values that correspond to somewhat weak IV's, but not irrelevant IV's. For $\rho_{u v}=0$, the paper shows (analytically) that the AR test achieves the lower bound function. Hence, for $\rho_{u v}=0$, the probabilities that the CLR CS has infinite length exceed the lower bound by the same amounts as reported above for the difference between the infinite length probabilities of the CLR and AR CS's for several ( $k, \lambda_{v}$ ) values. On the other hand, for values of $\left|\rho_{u v}\right| \geq .7$, the CLR CS has probabilities of having infinite length that are close to the lower bound function, .010 or less and typically much less, for all $\left(k, \lambda_{v}\right)$ combinations considered. For values of $\left|\rho_{u v}\right| \geq .7$, the AR CS has probabilities of having infinite length that are often far from the lower bound. For $\left|\rho_{u v}\right|=.9$ and certain values of $\lambda_{v}$, they are as large as $.084, .196, .280, .353$, and .422 for $k=2,5,10,20$, and 40 , respectively ${ }^{2}$

The AMS numerical results did not detect scenarios where the CLR test's power is off the two-

[^2]sided power envelope because AMS focussed on power for a fixed null hypothesis and a wide range of alternative values, whereas the probability that CS has infinite length depends on underlying tests' power for a fixed true parameter and arbitraily distant null hypothesis values. As discussed in Section 4 below, power in these two scenarios is different.

AMS reports results for only two values of the correlation $\rho_{\Omega}$ between the reduced-form errors, viz., $\rho_{\Omega}=.5$ and .95 . However, this is not the reason that AMS did not detect scenarios where the CLR test's power is noticeably off the two-sided power envelope. Figure SM-I in the Supplemental Material provides graphs that are the same as in AMS, but with $\rho_{\Omega}=0$, rather than $\rho_{\Omega}=.5$ or .95 . Even for $\rho_{\Omega}=0$, the power of the CLR test is close to the POIS2 power envelope in the scenarios considered, viz., .0110 or less. Note that $\rho_{\Omega}=0$ is the $\rho_{\Omega}$ value that yields many of the largest differences between the power of the CLR test and the POIS2 power envelope found in this paper when the true $\beta^{*}=0$ is fixed and the null value $\beta_{0}$ varies.

Fourth, the paper derives new optimality properties of the CLR and Lagrange multiplier (LM) tests when $\rho_{u v} \rightarrow \pm 1$ or $\rho_{\Omega} \rightarrow \pm 1$ with other parameters fixed at any values (with non-zero concentration parameter). In particular, optimality holds for fixed finite non-zero values of the concentration parameter. Optimality here is in the class of invariant similar tests or similar tests and employs the two-sided AE power envelope of AMS. These results are empirically relevant because they are consistent with the numerical results that show that the CLR test is close to the power envelope when $\left|\rho_{u v}\right|$ is large, viz., .7 and .9, but not extremely close to one.

These optimality results hold because taking $\rho_{u v} \rightarrow \pm 1$ or $\rho_{\Omega} \rightarrow \pm 1$ with other parameters fixed drives the length of the mean vector of the conditioning statistic $T$, as defined in AMS and below, to infinity. This is the same mechanism that yields asymptotic optimality of the CLR and LM tests when the concentration parameter goes to infinity as $n \rightarrow \infty$ (i.e., under strong or semi-strong IV's). The results show that arbitrarily large values of the concentration parameter are not needed for limiting optimality of the CLR and LM tests.

Fifth, we simulate power differences (PD's) between the two-sided AE power envelope of AMS and the power of the CLR test for a fixed alternative value $\beta_{*}$ and a range of finite null values $\beta_{0}$ (rather than the PD's as $\beta_{0} \rightarrow \pm \infty$ discussed above). These PD's are equivalent to the false coverage probability differences between the CLR CS and the corresponding infeasible optimal CS for a fixed true value $\beta_{*}$ at incorrect values $\beta_{0}$. We consider a wide range of ( $\beta_{0}, \lambda_{v}, \rho_{u v}, k$ ) values. The maximum (over $\beta_{0}$ and $\lambda_{v}$ values) PD's range between [.016, .061] over the ( $\rho_{u v}, k$ ) values considered. On the other hand, the average (over $\beta_{0}$ and $\lambda$ values) PD's only range between [.002, .016]. This indicates that, although there are some $\left(\beta_{0}, \lambda\right)$ values at which the CLR test is noticeably off the power envelope, on average the CLR test's power is not far from the power
envelope. The maximum PD's over $\left(\beta_{0}, \lambda\right)$ are found to increase in $k$ and decrease in $\left|\rho_{u v}\right|$. The $\lambda_{v}$ values at which the maxima are obtained are found to (weakly) increase with $k$ and decrease in $\left|\rho_{u v}\right|$. The $\left|\beta_{0}\right|$ values at which the maxima are obtained are found to be independent of $k$ and decrease in $\left|\rho_{u v}\right|$.

Sixth, the paper considers a weighted average power (WAP) envelope with a uniform weight function over a grid of concentration parameter values $\lambda_{v}$ and the same two-point AE weight function over $(\beta, \lambda)$ as in AMS. We refer to this as the WAP2 envelope. We determine numerically how close the power of the CLR test is to the WAP2 envelope. We find that the difference between the WAP2 envelope and the average power of the CLR test is in the range of [.001,.007] over all of the $\left(\beta_{0}, \beta_{*}, \rho_{u v}, k\right)$ values that we consider. Hence, the average power of the CLR test is quite close to the WAP2 envelope.

Other papers in the literature that consider WAP include Wald (1943), Andrews and Ploberger (1994), Andrews (1998), Moreira and Moreira (2013), Elliott, Müller, and Watson (2015), and papers referenced above. The WAP2 envelope considered here is closest to the WAP envelopes in Wald (1943), AMS, and CHJ because the other papers listed put a weight function over all of the parameters in the alternative hypothesis, which yields a single weighted alternative density. In contrast, the WAP2 envelope, Wald (1943), AMS, and CHJ consider a family of weight functions over disjoint sets of parameters in the alternative hypothesis, which yields a WAP envelope.

In conclusion, based on our findings, we recommend use of the CLR test and CS. More specifically, we recommend using heteroskedasticity-robust versions of these procedures that have the same asymptotic properties as these procedures under homoskedasticity. For example, such tests are given in Andrews, Moreira, and Stock (2004) and Andrews and Guggenberger (2015). The CLR CS has higher probability of having infinite length than the AR CS in some scenarios, and the CLR test is not a UMP two-sided invariant similar test. But, no such UMP test exists and the CLR CS is close to the two-sided AE power envelope for invariant similar tests when $\left|\rho_{u v}\right|$ is not close to zero and is close to the WAP2 envelope for all values of $\left|\rho_{u v}\right|$.

Finally, we point out that the results of this paper illustrate a point that applies more generally than in the linear IV model. In weak identification scenarios, where CS's may have infinite length (or may be bounded only due to bounds on the parameter space), good test performance at a priori implausible parameter values is important for good CS performance at plausible parameter values. More specifically, the probability under an a priori plausible parameter value $\beta_{*}$ that a CS has infinite length depends on the power of the test used to construct the CS against $\beta_{*}$ when the null value $\left|\beta_{0}\right|$ is arbitrarily large, which may be an a priori implausible null value.

For the computation of CLR CS's, see Mikusheva (2010). For a formula for the power of the

CLR test, see Hillier (2009).
The paper is organized as follows. Section 2 specifies the model. Section 3 defines the class of invariant similar tests. Section 4 contrasts the power properties of tests in the scenario where $\beta_{0}$ is fixed and $\beta_{*}$ takes on large (absolute) values, with the scenario where $\beta_{*}$ is fixed and $\beta_{0}$ takes on large (absolute) values. Section 5 provides a formula for the probability that a CS has infinite length. Section 6 derives a lower bound on the probability that a CS constructed using two-sided invariant similar tests has infinite length. Section 7 reports differences between the probability that the CLR CS has infinite length and the lower bound derived in the previous section. Section 8 proves the optimality results for the CLR test described above. Section 9 reports differences between the power of CLR tests and the two-sided AE power bound of AMS for a wide range of parameter configurations. Section 10 provides comparisons of the power of the CLR test to the WAP2 power envelope described above. Proofs and additional theoretical and numerical results are given in the Supplemental Material (SM).

## 2 Model

We consider the same model as in Andrews, Moreira, and Stock (2004, 2006) (AMS04, AMS) but, for simplicity and without loss of generality (wlog), without any exogenous variables. The model has one rhs endogenous variable, $k$ instrumental variables (IV's), and normal errors with known reduced-form error variance matrix. The model consists of a structural equation and a reduced-form equation:

$$
\begin{equation*}
y_{1}=y_{2} \beta+u \text { and } y_{2}=Z \pi+v_{2}, \tag{2.1}
\end{equation*}
$$

where $y_{1}, y_{2} \in R^{n}$ and $Z \in R^{n \times k}$ are observed variables; $u, v_{2} \in R^{n}$ are unobserved errors; and $\beta \in R$ and $\pi \in R^{k}$ are unknown parameters. The IV matrix $Z$ is fixed (i.e., non-stochastic) and has full column rank $k$. The $n \times 2$ matrix of errors [u:v $v_{2}$ ] is i.i.d. across rows with each row having a mean zero bivariate normal distribution.

The two corresponding reduced-form equations are

$$
\begin{align*}
Y & :=\left[y_{1}: y_{2}\right]:=\left[Z \pi \beta+v_{1}: Z \pi+v_{2}\right]=Z \pi a^{\prime}+V, \text { where } \\
V & :=\left[v_{1}: v_{2}\right]=\left[u+v_{2} \beta: v_{2}\right], \text { and } a:=(\beta, 1)^{\prime} . \tag{2.2}
\end{align*}
$$

The distribution of $Y \in R^{n \times 2}$ is multivariate normal with mean matrix $Z \pi a^{\prime}$, independence across rows, and reduced-form variance matrix $\Omega \in R^{2 \times 2}$ for each row. For the purposes of obtaining exact finite-sample results, we suppose $\Omega$ is known. As in AMS, asymptotic results for unknown $\Omega$
and weak IV's are the same as the exact results with known $\Omega$. The parameter space for $\theta=\left(\beta, \pi^{\prime}\right)^{\prime}$ is $R^{k+1}$.

We are interested in tests of the null hypothesis $H_{0}: \beta=\beta_{0}$ and CS's for $\beta$.
As shown in AMS, $Z^{\prime} Y$ is a sufficient statistic for $\left(\beta, \pi^{\prime}\right)^{\prime}$. As in Moreira (2003) and AMS, we consider a one-to-one transformation $[S: T]$ of $Z^{\prime} Y$ :

$$
\begin{align*}
S & :=\left(Z^{\prime} Z\right)^{-1 / 2} Z^{\prime} Y b_{0} \cdot\left(b_{0}^{\prime} \Omega b_{0}\right)^{-1 / 2} \sim N\left(c_{\beta}\left(\beta_{0}, \Omega\right) \cdot \mu_{\pi}, I_{k}\right) \text { and } \\
T & :=\left(Z^{\prime} Z\right)^{-1 / 2} Z^{\prime} Y \Omega^{-1} a_{0} \cdot\left(a_{0}^{\prime} \Omega^{-1} a_{0}\right)^{-1 / 2} \sim N\left(d_{\beta}\left(\beta_{0}, \Omega\right) \cdot \mu_{\pi}, I_{k}\right), \text { where } \\
b_{0} & :=\left(1,-\beta_{0}\right)^{\prime}, a_{0}:=\left(\beta_{0}, 1\right)^{\prime}, \mu_{\pi}:=\left(Z^{\prime} Z\right)^{1 / 2} \pi \in R^{k}, \\
c_{\beta}\left(\beta_{0}, \Omega\right) & :=\left(\beta-\beta_{0}\right) \cdot\left(b_{0}^{\prime} \Omega b_{0}\right)^{-1 / 2} \in R, \\
d_{\beta}\left(\beta_{0}, \Omega\right) & :=b^{\prime} \Omega b_{0} \cdot\left(b_{0}^{\prime} \Omega b_{0}\right)^{-1 / 2} \operatorname{det}(\Omega)^{-1 / 2} \in R, \text { and } b=(1,-\beta)^{\prime} . \tag{2.3}
\end{align*}
$$

As defined, $S$ and $T$ are independent. Note that $S$ and $T$ depend on the null hypothesis value $\beta_{0}$.

## 3 Invariant Similar Tests

As in Hillier (1984) and AMS, we consider tests that are invariant to orthonormal transformations of $[S: T]$, i.e., $[S: T] \rightarrow[F S: F T]$ for a $k \times k$ orthogonal matrix $F$. The $2 \times 2$ matrix $Q$ is a maximal invariant, where

$$
Q=[S: T]^{\prime}[S: T]=\left[\begin{array}{cc}
S^{\prime} S & S^{\prime} T  \tag{3.1}\\
S^{\prime} T & T^{\prime} T
\end{array}\right]=\left[\begin{array}{ll}
Q_{S} & Q_{S T} \\
Q_{S T} & Q_{T}
\end{array}\right] \text { and } Q_{1}=\binom{S^{\prime} S}{S^{\prime} T}=\binom{Q_{S}}{Q_{S T}}
$$

e.g., see Theorem 1 of AMS. Note that $Q_{1}$ is the first column of $Q$ and the matrix $Q$ depends on the null value $\beta_{0}$.

The statistic $Q$ has a non-central Wishart distribution because $[S: T]$ is a multivariate normal matrix that has independent rows and common covariance matrix across rows. The distribution of $Q$ depends on $\pi$ only through the scalar

$$
\begin{equation*}
\lambda:=\pi^{\prime} Z^{\prime} Z \pi \geq 0 \tag{3.2}
\end{equation*}
$$

Leading examples of invariant identification-robust tests in the literature include the AR test, the LM test of Kleibergen (2002) and Moreira (2009), and the CLR test of Moreira (2003). The latter test depends on the standard LR test statistic coupled with a "conditional" critical value
that depends on $Q_{T}$. The LR, LM, and AR test statistics are

$$
\begin{align*}
L R & :=\frac{1}{2}\left(Q_{S}-Q_{T}+\sqrt{\left(Q_{S}-Q_{T}\right)^{2}+4 Q_{S T}^{2}}\right), \\
L M & :=Q_{S T}^{2} / Q_{T}=\left(S^{\prime} T\right)^{2} / T^{\prime} T, \text { and } A R:=Q_{S} / k=S^{\prime} S / k \tag{3.3}
\end{align*}
$$

The critical values for the $L M$ and $A R$ tests are $\chi_{1,1-\alpha}^{2}$ and $\chi_{k, 1-\alpha}^{2} / k$, respectively, where $\chi_{m, 1-\alpha}^{2}$ denotes the $1-\alpha$ quantile of the $\chi^{2}$ distribution with $m$ degrees of freedom.

A test based on the maximal invariant $Q$ is similar if its null rejection rate does not depend on the parameter $\pi$ that determines the strength of the IV's $Z$. As in Moreira (2003), the class of invariant similar tests is specified as follows. Let the $[0,1]$-valued statistic $\phi(Q)$ denote a (possibly randomized) test that depends on the maximal invariant $Q$. An invariant test $\phi(Q)$ is similar with significance level $\alpha$ if and only if $E_{\beta_{0}}\left(\phi(Q) \mid Q_{T}=q_{T}\right)=\alpha$ for almost all $q_{T}>0$ (with respect to Lebesgue measure), where $E_{\beta_{0}}\left(\cdot \mid Q_{T}=q_{T}\right)$ denotes conditional expectation given $Q_{T}=q_{T}$ when $\beta=\beta_{0}$ (which does not depend on $\pi$ ).

The CLR test rejects the null hypothesis when

$$
\begin{equation*}
L R>\kappa_{L R, \alpha}\left(Q_{T}\right) \tag{3.4}
\end{equation*}
$$

where $\kappa_{L R, \alpha}\left(Q_{T}\right)$ is defined to satisfy $P_{\beta_{0}}\left(L R>\kappa_{L R, \alpha}\left(Q_{T}\right) \mid Q_{T}=q_{T}\right)=\alpha$ and the conditional distribution of $Q_{1}=\left(Q_{S}, Q_{S T}\right)^{\prime}$ given $Q_{T}$ is specified in AMS and in 12.3) in the SM.

The invariance condition discussed above is a rotational invariance condition. In some cases, we also consider a sign invariance condition. A test that depends on $[S: T]$ is sign invariant if it is invariant to the transformation $[S: T] \rightarrow[-S: T]$. A rotation invariant test is also sign invariant if it depends on $Q_{S T}$ only through $\left|Q_{S T}\right|$. Tests that are sign invariant are two-sided tests. In fact, AMS shows that the two-sided AE power envelope is identical to the power envelope generated by sign and rotation invariant tests, see (4.11) in AMS.

For simplicity, we will use the term invariant test to mean a rotation invariant test and the term sign and rotation invariant test to describe a test that satisfies both invariance conditions.

The paper also provides some results that apply to tests that satisfy no invariance properties. A test $\phi([S: T])$ (that is not necessarily invariant) is similar with significance level $\alpha$ if and only if $E_{\beta_{0}}(\phi([S: T]) \mid T=t)=\alpha$ for almost all $t$ (with respect to Lebesgue measure), where $E_{\beta_{0}}(\cdot \mid T=t$ ) denotes conditional expectation given $T=t$ when $\beta=\beta_{0}$ (which does not depend on $\pi$ ), see Moreira (2009).

## 4 Power Against Distant Alternatives Compared to Distant Null Hypotheses

In this section, we consider the power properties of tests when $\left|\beta_{*}-\beta_{0}\right|$ is large, where $\beta_{*}$ denotes the true value of $\beta$. We compare scenario 1 , where $\beta_{0}$ and $\Omega$ are fixed and $\beta_{*}$ takes on large (absolute) values, to scenario 2 , where $\beta_{*}$ and $\Omega$ are fixed and $\beta_{0}$ takes on large (absolute) values. Scenario 1 yields the power function of a test against distant alternatives. Scenario 2 yields the false coverage probabilities of the CS constructed using the test for distant null hypotheses (from the true parameter value $\beta_{*}$ ). We show that, while power goes to one in scenario 1 as $\beta_{*} \rightarrow \pm \infty$ for fixed $\beta_{0}$ for standard tests, it is not true that power goes to one in scenario 2 as $\beta_{0} \rightarrow \pm \infty$ for fixed $\beta_{*}$. Hence, the power properties of tests are quite different in scenarios 1 and 2 .

The numerical power function and power envelope calculations in AMS are all of the type in scenario 1. The difference in power properties of tests between scenarios 1 and 2 suggests that it is worth exploring the properties of tests in scenarios of the latter type as well. We do this in the paper and show that the finding of AMS that the CLR test is essentially on the two-sided AE power envelope and is always at least as powerful as the AR test does not hold when one considers a broader range of null and alternative hypothesis values $\left(\beta_{0}, \beta_{*}\right)$ than considered in the numerical results in AMS.

It is convenient to consider the AR test, which is the simplest test. The AR test rejects $H_{0}: \beta=\beta_{0}$ when $S^{\prime} S>\chi_{k, \alpha}^{2}$. When the true value is $\beta$, the distribution of the $S^{\prime} S$ statistic is noncentral $\chi^{2}$ with noncentrality parameter

$$
\begin{equation*}
c_{\beta}^{2}\left(\beta_{0}, \Omega\right) \cdot \lambda \tag{4.1}
\end{equation*}
$$

and $k$ degrees of freedom. For the fixed null hypothesis $H_{0}: \beta=\beta_{0}$, fixed $\Omega$, and fixed $\lambda$, the power at the alternative hypothesis value $\beta_{*}$ is determined by $c_{\beta_{*}}^{2}\left(\beta_{0}, \Omega\right)$. We have

$$
\begin{equation*}
\lim _{\left|\beta_{*}\right| \rightarrow \infty} c_{\beta_{*}}^{2}\left(\beta_{0}, \Omega\right)=\lim _{\left|\beta_{*}\right| \rightarrow \infty}\left(\beta_{*}-\beta_{0}\right)^{2} \cdot\left(b_{0}^{\prime} \Omega b_{0}\right)^{-1}=\infty \tag{4.2}
\end{equation*}
$$

Hence, the power of the AR test goes to one as $\left|\beta_{*}\right| \rightarrow \infty$.
On the other hand, if one fixes the alternative hypothesis value $\beta_{*}$ and one considers the limit
as $\left|\beta_{0}\right| \rightarrow \infty$, then one obtains

$$
\begin{align*}
\lim _{\left|\beta_{0}\right| \rightarrow \infty} c_{\beta_{*}}^{2}\left(\beta_{0}, \Omega\right) & =\lim _{\left|\beta_{0}\right| \rightarrow \infty}\left(\beta_{*}-\beta_{0}\right)^{2} \cdot\left(b_{0}^{\prime} \Omega b_{0}\right)^{-1} \\
& =\lim _{\left|\beta_{0}\right| \rightarrow \infty}\left(\beta_{*}-\beta_{0}\right)^{2} \cdot\left(\omega_{1}^{2}-2 \omega_{12} \beta_{0}+\omega_{2}^{2} \beta_{0}^{2}\right)^{-1} \\
& =1 / \omega_{2}^{2}, \tag{4.3}
\end{align*}
$$

where $\omega_{1}^{2}, \omega_{2}^{2}$, and $\omega_{12}$ denote the $(1,1),(2,2)$, and $(1,2)$ elements of $\Omega$, respectively. Hence, the power of the AR test does not go to one as $\left|\beta_{0}\right| \rightarrow \infty$ even though $\left|\beta_{0}-\beta_{*}\right| \rightarrow \infty$. This occurs because the structural equation error variance, $\operatorname{Var}\left(u_{i}\right)=b_{0}^{\prime} \Omega b_{0}$, diverges to infinity as $\left|\beta_{0}\right| \rightarrow \infty$.

The differing results in (4.2) and (4.3) is easy to show for the AR test, but it also holds for Kleibergen's and Moreira's LM test and Moreira's CLR test. For brevity, we do not provide such results here.

Note that Davidson and MacKinnon (2008, Sec. 4) provide different, but somewhat related, results to those in this section ${ }^{3}$ They consider power when $\beta_{0}$ is fixed and $\beta_{*}$ takes on large (absolute) values (as in scenario 1) but when the correlation $\rho_{u v}$ (between the structural-equation error $u$ and the reduced-form error $v_{2}$ ) is held fixed and the structural equation error variance is estimated. In contrast, the results given here are for the case where the correlation $\rho_{\Omega}$ (between the reduced-form errors $v_{1}$ and $v_{2}$ ) is held fixed because $\rho_{\Omega}$ can be consistently estimated and, hence, in large samples can be treated as fixed and known. This is not true for $\rho_{u v}$. In the Davidson and MacKinnon (2008) scenario, power does not go to one as $\beta_{*} \rightarrow \pm \infty$ for fixed $\beta_{0}$.

## 5 Probability That a Confidence Set Has Infinite Length

In this section, we show that the probability that a CS has infinite length is given by one minus the power of the test used to construct the CS as the null value $\beta_{0}$ of the test goes to $\infty$ or $-\infty$. This provides motivation for interest in the power of tests as $\beta_{0} \rightarrow \pm \infty$. It shows why high power against distant null hypotheses is highly desirable.

We sometimes make the dependence of $Q, S$, and $T$ on $Y$ and $\beta_{0}$ explicit and write

$$
\begin{equation*}
Q=Q_{\beta_{0}}(Y)=\left[S_{\beta_{0}}(Y): T_{\beta_{0}}(Y)\right]^{\prime}\left[S_{\beta_{0}}(Y): T_{\beta_{0}}(Y)\right] \tag{5.1}
\end{equation*}
$$

We denote the $(1,1),(1,2)$, and $(2,2)$ elements of $Q_{\beta_{0}}(Y)$ by $Q_{S, \beta_{0}}(Y), Q_{S T, \beta_{0}}(Y)$, and $Q_{T, \beta_{0}}(Y)$, respectively.

[^3]Let

$$
\begin{equation*}
\phi\left(Q_{\beta_{0}}(Y)\right)=1\left(\mathcal{T}\left(Q_{\beta_{0}}(Y)\right)>c v\left(Q_{T \beta_{0}}(Y)\right)\right) \tag{5.2}
\end{equation*}
$$

be a (nonrandomized) invariant similar level $\alpha$ test for testing $H_{0}: \beta=\beta_{0}$ for fixed known $\Omega$, where $\mathcal{T}\left(Q_{\beta_{0}}(Y)\right)$ is a test statistic and $c v\left(Q_{T \beta_{0}}(Y)\right)$ is a (possibly data-dependent) critical value. Examples include the AR, LM, and CLR tests in 3.3 . Let $C S_{\phi}$ be the level $1-\alpha$ CS corresponding to $\phi$. That is,

$$
\begin{equation*}
C S_{\phi}(Y)=\left\{\beta_{0}: \phi\left(Q_{\beta_{0}}(Y)\right)=0\right\} \tag{5.3}
\end{equation*}
$$

We say $C S_{\phi}(Y)$ has right (or left) infinite length, which we denote by $R \operatorname{Length}\left(C S_{\phi}(Y)\right)=\infty$ (or LLength $\left(C S_{\phi}(Y)\right)=\infty$ ), if

$$
\begin{equation*}
\exists K(Y)<\infty \text { such that } \beta \in C S_{\phi}(Y) \forall \beta \geq K(Y)(\text { or } \forall \beta \leq-K(Y)) \tag{5.4}
\end{equation*}
$$

We say $C S_{\phi}(Y)$ has infinite length, which we denote by $\operatorname{Length}\left(C S_{\phi}(Y)\right)=\infty$, if it has right and left infinite lengths. A CS with infinite length contains a set of the form $\left(-\infty, K_{1}(Y)\right) \cup\left(K_{2}(Y), \infty\right)$ for some $-\infty<K_{1}(Y) \leq K_{2}(Y)<\infty$.

Let $P_{\beta_{*}, \pi, \Omega}(\cdot)$ denote probability for events determined by $Y$ when $Y$ has a multivariate normal distribution with means matrix $\left[\pi \beta_{*}: \pi\right] \in R^{2 k}$, independence across rows, and variance matrix $\Omega$ for each row. Let $P_{\beta_{*}, \beta_{0}, \lambda, \Omega}(\cdot)$ denote probability for events determined by $Q$ when $Q:=[S: T]^{\prime}[S:$ $T]$ and $[S: T]$ has the multivariate normal distribution in 2.3 with $\beta=\beta_{*}$ and $\lambda=\mu_{\pi}^{\prime} \mu_{\pi}$. In this case, $Q$ has a noncentral Wishart distribution whose density is given in 12.2 in the SM .

For fixed true value $\beta_{*}$ and reduced-form variance matrix $\Omega$, let $\Sigma_{*}$ denote the corresponding structural variance matrix of each row of $\left[u: v_{2}\right]$. Let $\rho_{u v}$ denote the correlation between the structural and reduced-form errors, i.e., the correlation corresponding to $\Sigma_{*}$. Some calculations show that

$$
\begin{align*}
\rho_{u v} & =\frac{\omega_{12}-\omega_{2}^{2} \beta_{*}}{\left(\omega_{1}^{2}-2 \omega_{12} \beta_{*}+\omega_{2}^{2} \beta_{*}^{2}\right)^{1 / 2} \omega_{2}} \text { and } \\
\Sigma_{*} & =\left[\begin{array}{cc}
\sigma_{u}^{2} & \sigma_{u} \sigma_{v} \rho_{u v} \\
\sigma_{u} \sigma_{v} \rho_{u v} & \sigma_{v}^{2}
\end{array}\right]=\left[\begin{array}{cc}
\omega_{1}^{2}-2 \omega_{12} \beta_{*}+\omega_{2}^{2} \beta_{*}^{2} & \omega_{12}-\omega_{2}^{2} \beta_{*} \\
\omega_{12}-\omega_{2}^{2} \beta_{*} & \omega_{2}^{2}
\end{array}\right], \tag{5.5}
\end{align*}
$$

where $\omega_{1}^{2}, \omega_{2}^{2}$, and $\omega_{12}$ the elements of $\Omega$, see 12.9 in the SM . By the first equality in the second line of (5.5), $\sigma_{u}^{2}=\operatorname{Var}\left(u_{i}\right), \sigma_{v}^{2}=\operatorname{Var}\left(v_{2 i}\right)$, and $\rho_{u v}=\operatorname{Corr}\left(u_{i}, v_{2 i}\right)$.

It is shown in Lemma 16.1 in the SM that the limit as $\beta_{0} \rightarrow \pm \infty$ of $Q_{\beta_{0}}(Y)$ is

$$
Q_{ \pm \infty}(Y):=\left[\begin{array}{cc}
e_{2}^{\prime} Y^{\prime} P_{Z} Y e_{2} \cdot \frac{1}{\sigma_{v}^{2}} & e_{2}^{\prime} Y^{\prime} P_{Z} Y \Omega^{-1} e_{1} \cdot \frac{\mp\left(1-\rho_{u v}^{2}\right)^{1 / 2} \sigma_{u}}{\sigma_{v}}  \tag{5.6}\\
e_{2}^{\prime} Y^{\prime} P_{Z} Y \Omega^{-1} e_{1} \cdot \frac{\mp\left(1-\rho_{u v}\right)^{1 / 2} \sigma_{u}}{\sigma_{v}} & e_{1}^{\prime} \Omega^{-1} Y^{\prime} P_{Z} Y \Omega^{-1} e_{1} \cdot\left(1-\rho_{u v}^{2}\right) \sigma_{u}^{2}
\end{array}\right],
$$

where $P_{Z}:=Z\left(Z^{\prime} Z\right)^{-1} Z^{\prime}, e_{1}:=(1,0)^{\prime}$, and $e_{2}:=(0,1)^{\prime}$. Let $Q_{T, \pm \infty}(Y)$ denote the ( 2,2 ) element of $Q_{ \pm \infty}(Y)$. It is also shown in Lemma 16.1 in the SM that $Q_{ \pm \infty}(Y)$ has a noncentral Wishart distribution with means matrix $\mp \mu_{\pi}\left(1 / \sigma_{v}, \rho_{u v} /\left(\sigma_{v}\left(1-\rho_{u v}^{2}\right)^{1 / 2}\right)\right) \in R^{k \times 2}$ and identity variance matrix 4

Theorem 5.1 Suppose $C S_{\phi}(Y)$ is a CS based on invariant level $\alpha$ tests $\phi\left(Q_{\beta_{0}}(Y)\right)$ whose test statistic and critical value functions, $\mathcal{T}(q)$ and $c v\left(q_{T}\right)$, respectively, are continuous at all positive definite $2 \times 2$ matrices $q$ and positive constants $q_{T}, P_{\beta_{*}, \pi, \Omega}\left(\mathcal{T}\left(Q_{c}(Y)\right)=c v\left(Q_{T, c}(Y)\right)\right)=0$ for $c=+\infty$ in parts (a) and (c) below and $c=-\infty$ in part (b) below. Then, for all $\left(\beta_{*}, \lambda, \Omega\right)$,
(a) $P_{\beta_{*}, \pi, \Omega}\left(R L e n g t h\left(C S_{\phi}(Y)\right)=\infty\right)=1-\lim _{\beta_{0} \rightarrow \infty} P_{\beta_{*}, \beta_{0}, \lambda, \Omega}(\phi(Q)=1)$,
(b) $P_{\beta_{*}, \pi, \Omega}\left(\operatorname{LLength}\left(\operatorname{CS}_{\phi}(Y)\right)=\infty\right)=1-\lim _{\beta_{0} \rightarrow-\infty} P_{\beta_{*}, \beta_{0}, \lambda, \Omega}(\phi(Q)=1)$, and
(c) if the tests are sign invariant, i.e., $\mathcal{T}(Q)$ depends on $Q_{S T}$ only through $\left|Q_{S T}\right|$, then $P_{\beta_{*}, \pi, \Omega}\left(\operatorname{Length}\left(C S_{\phi}(Y)\right)=\infty\right)=1-\lim _{\beta_{0} \rightarrow \pm \infty} P_{\beta_{*}, \beta_{0}, \lambda, \Omega}(\phi(Q)=1)$.

Comments. (i). For the AR, LM, and LR tests, the continuity conditions on $\mathcal{T}(q)$ and $c v\left(q_{T}\right)$ hold given their simple functional forms in (3.3) using the assumption that $q_{T}>0$ for the LM statistic and using the continuity of $\kappa_{L R, \alpha}\left(q_{T}\right)$, which holds by the argument in the proof of Thm. 10.1 in Andrews and Guggenberger (2016). We have $P_{\beta_{*}, \pi, \Omega}\left(\mathcal{T}\left(Q_{ \pm \infty}(Y)\right)=c v\left(Q_{T, \pm \infty}(Y)\right)\right)=0$ for the AR and LM tests because $c v\left(Q_{T, \pm \infty}(Y)\right)$ is a constant and $\mathcal{T}\left(Q_{ \pm \infty}(Y)\right)$ is absolutely continuous with respect to Lebesgue measure. For the CLR test, $P_{\beta_{*}, \pi, \Omega}\left(\mathcal{T}\left(Q_{ \pm \infty}(Y)\right)=c v\left(Q_{T, \pm \infty}(Y)\right)\right)=0$ by the argument given in the proof of Theorem 6.4 in the SM. The AR, LM, and CLR test statistics are sign invariant. Hence, parts (a)-(c) of Theorem 5.1 apply to these tests. Theorem 6.4 (a)-(c) below provides formulae for the quantities $\lim _{\beta_{0} \rightarrow \pm \infty} P_{\beta_{*}, \beta_{0}, \lambda, \Omega}(\phi(Q)=1)$, which appear in Theorem 5.1 . for the AR, LM, and CLR tests.
(ii). Comment (iii) to Theorem 6.2 below provides a lower bound on $1-\lim _{\beta_{0} \rightarrow \infty} P_{\beta_{*}, \beta_{0}, \lambda, \Omega}(\phi)(Q)$ $=1$ ) over all sign and rotation invariant similar level $\alpha$ tests. Combining this with Theorem 5.1(c) yields a lower bound on the probability that a $\operatorname{CS} C S_{\phi}(Y)$ based on such tests has Length $=\infty$. The lower bound on the probability that Length $=\infty$ is greater than the lower bound on the probability that RLength $=\infty$ (or that LLength $=\infty$ ) unless $\rho_{u v}=0$ (in which case it turns out that they are equal).

[^4]Theorem 13.1 in the SM provides lower bounds on $1-\lim _{\beta_{0} \rightarrow \pm \infty} P_{\beta_{*}, \beta_{0}, \lambda, \Omega}(\phi(Q)=1)$ over all invariant similar level $\alpha$ tests. Combining these with Theorem 5.1(a) and (b) yields lower bounds on the probabilities that a $\operatorname{CS} C S_{\phi}(Y)$ has RLength $=\infty$ based on $\beta_{0} \rightarrow \infty$ and LLength $=\infty$ based on $\beta_{0} \rightarrow-\infty$.
(iii). Note that Theorem 5.1 does not impose similarity, just invariance. The results of Theorem 5.1 (a) and (b) also hold for a $C S_{\phi}(Y)$ that is based on level $\alpha$ tests that are not invariant. Denote such tests by $\phi\left(S_{\beta_{0}}(Y), T_{\beta_{0}}(Y)\right)$ and suppose their test statistic and critical value functions, $\mathcal{T}(s, t)$ and $c v(t)$, respectively, are continuous at all $k \times 2$ matrices [ $s: t$ ] and $k$ vectors $t$ and satisfy $P_{\beta_{*}, \pi, \Omega}\left(\mathcal{T}\left(S_{c}(Y), T_{c}(Y)\right)=c v\left(T_{c}(Y)\right)\right)=0$ for $c=+\infty$, where $S_{ \pm \infty}(Y):=\mp\left(Z^{\prime} Z\right)^{-1 / 2} Z^{\prime} Y e_{2} / \sigma_{v}$ and $T_{ \pm \infty}(Y):= \pm\left(Z^{\prime} Z\right)^{-1 / 2} Z^{\prime} Y \Omega^{-1} e_{1} \cdot\left(1-\rho_{u v}^{2}\right)^{1 / 2} \sigma_{u}$. In this case, $P_{\beta_{*}, \pi, \Omega}\left(R L e n g t h\left(C S_{\phi}(Y)\right)=\right.$ $\infty)=1-\lim _{\beta_{0} \rightarrow \infty} P_{\beta_{*}, \beta_{0}, \pi, \Omega}(\phi([S: T])=1)$ and likewise with LLength $(\cdot), \beta_{0} \rightarrow-\infty$, and $c=-\infty$ in place of $R \operatorname{Length}(\cdot), \beta_{0} \rightarrow \infty$, and $c=+\infty$. If, in addition, the tests satisfy: $\mathcal{T}\left(S_{c}(Y), T_{c}(Y)\right) \leq$ $c v\left(T_{c}(Y)\right)$ for $c=+\infty$ iff the same inequality holds for $c=-\infty$, then Theorem 5.1(c) also holds. (These results hold by a straightforward modification of the proof of Theorem 5.1.)
(iv). By Dufour (1997), all CS's for $\beta$ with correct size must have positive probability of having infinite length (assuming $\pi$ is not bounded away from 0 ). In consequence, expected CS length, which is a standard measure of the performance of a CS, is infinite for all identificationrobust CS's. Due to this, Mikusheva (2010) compares CS's based on their expected truncated lengths for various truncation values. The result of Theorem 6.2 below implies that, for two CS's where the rhs of Theorem 6.2 (c) is smaller for the first CS than the second, the first CS has smaller expected truncated length than the second for sufficiently large truncation values.
(v) Section 25 in the Supplemental Material extends Theorem 5.1 to the linear IV model that allows for heteroskedasticity and autocorrelation (HC) in the errors, as in Moriera and Ridder (2017).

## 6 Power Bound as $\boldsymbol{\beta}_{0} \rightarrow \pm \infty$

In this section, we provide two-sided AE power bounds for invariant similar tests as $\beta_{0} \rightarrow \pm \infty$ for fixed $\beta_{*}$. We obtain these bounds by finding the limit of the power bounds in Theorem 3 of AMS as $\beta_{0} \rightarrow \pm \infty$. The power bounds also apply to the larger class of similar tests for which invariance is not imposed, provided power is averaged over $\mu_{\pi} /\left\|\mu_{\pi}\right\|$ vectors using the uniform distribution on the unit sphere in $R^{k}$, as in CHJ.

Using Theorem 5.1, these results are used to obtain bounds on the probabilities that CS's constructed using sign and rotation invariant similar tests have infinite length. They also are used
to obtain bounds on certain average probabilities that similar invariant tests and similar tests have infinite right (or left) length.

This section also determines the power of the AR, LM, and CLR tests as $\beta_{0} \rightarrow \pm \infty$ and the probabilities that AR, LM, and CLR CS's have infinite length.

### 6.1 Density of Q as $\boldsymbol{\beta}_{0} \rightarrow \pm \infty$

The density of $Q:=[S: T]^{\prime}[S: T]$ when $[S: T]$ has the multivariate normal distribution in (2.3) only depends on $\pi$ through $\lambda:=\mu_{\pi}^{\prime} \mu_{\pi}$. Let $f_{Q}\left(q ; \beta_{*}, \beta_{0}, \lambda, \Omega\right)$ denote this density when $\beta=\beta_{*}$. It is a noncentral Wishart density with means matrix of rank one and identity covariance matrix, which was first derived by Anderson (1946, eqn. (6)). An explicit expression for $f_{Q}\left(q ; \beta_{*}, \beta_{0}, \lambda, \Omega\right)$ is given in 12.2 in the SM.

Now, we determine the limit of the density $f_{Q}\left(q ; \beta_{*}, \beta_{0}, \lambda, \Omega\right)$ as $\beta_{0} \rightarrow \pm \infty$. Define

$$
\begin{equation*}
r_{u v}:=\frac{\rho_{u v}}{\left(1-\rho_{u v}^{2}\right)^{1 / 2}} \text { and } \lambda_{v}:=\lambda / \sigma_{v}^{2}=\mu_{\pi}^{\prime} \mu_{\pi} / \sigma_{v}^{2} \tag{6.1}
\end{equation*}
$$

Note that $\lambda_{v}$ is the concentration parameter, which indexes the strength of the IV's. Let $f_{Q}\left(q ; \rho_{u v}, \lambda_{v}\right)$ denote the density of $Q:=[S: T]^{\prime}[S: T]$ when $[S: T]$ has a multivariate normal distribution with means matrix

$$
\begin{equation*}
\mu_{\pi} \cdot\left(1 / \sigma_{v}, r_{u v} / \sigma_{v}\right) \in R^{k \times 2} \tag{6.2}
\end{equation*}
$$

all variances equal to one, and all covariances equal to zero. This density also is a noncentral Wishart density with means matrix of rank one and identity covariance matrix. The density depends on $r_{u v}, \sigma_{v}$, and $\pi$ only through $\rho_{u v}$ and $\lambda_{v}$. An explicit expression for $f_{Q}\left(q ; \rho_{u v}, \lambda_{v}\right)$ is given in (12.4) in Section 12.1 the SM.

Lemma 6.1 For any fixed $\left(\beta_{*}, \lambda, \Omega\right), \lim _{\beta_{0} \rightarrow \pm \infty} f_{Q}\left(q ; \beta_{*}, \beta_{0}, \lambda, \Omega\right)=f_{Q}\left(q ; \rho_{u v}, \lambda_{v}\right)$ for all $2 \times 2$ variance matrices $q$, where $\rho_{u v}$ and $\lambda_{v}$ are defined in (5.5) and (6.1), respectively.

Comment. Lemma 6.1 is proved by showing: $\lim _{\beta_{0} \rightarrow \pm \infty} c_{\beta_{*}}\left(\beta_{0}, \Omega\right)=\mp 1 / \sigma_{v}$ and $\lim _{\beta_{0} \rightarrow \pm \infty}$ $d_{\beta_{*}}\left(\beta_{0}, \Omega\right)= \pm \frac{\omega_{2}^{2} \beta_{*}-\omega_{12}}{\omega_{2}\left(\omega_{1}^{2} \omega_{2}^{2}-\omega_{12}^{2}\right)^{1 / 2}}=\mp \frac{\rho_{u v}}{\sigma_{v}\left(1-\rho_{u v}^{2}\right)^{1 / 2}}$, see Lemma 15.1 in the SM. When expressed in terms of $\Sigma_{*}$, the latter limit only depends on $\rho_{u v}, \sigma_{u}$, and $\sigma_{v}$ and its functional form is of a relatively simple multiplicative form.

Let $P_{\beta_{*}, \beta_{0}, \lambda, \Omega}(\cdot)$ and $P_{\rho_{u v}, \lambda_{v}}(\cdot)$ denote probabilities under the alternative hypothesis densities $f_{Q}\left(q ; \beta_{*}, \beta_{0}, \lambda, \Omega\right)$ and $f_{Q}\left(q ; \rho_{u v}, \lambda_{v}\right)$, respectively, defined above.

### 6.2 Two-Sided AE Power Bound as $\boldsymbol{\beta}_{0} \rightarrow \pm \infty$

AMS provides a two-sided power envelope for invariant similar tests based on maximizing average power against two points in the alternative hypothesis: $\left(\beta_{*}, \lambda\right)$ and $\left(\beta_{2 *}, \lambda_{2}\right)$. AMS refers to this as the two-sided AE power envelope because given one point $\left(\beta_{*}, \lambda\right)$, the second point $\left(\beta_{2 *}, \lambda_{2}\right)$ is the unique point such that the test that maximizes average power against these two points is a two-sided AE test under strong IV asymptotics. This power envelope is a function of $\left(\beta_{*}, \lambda\right)$.

Given $\left(\beta_{*}, \lambda\right)$, the second point $\left(\beta_{2 *}, \lambda_{2}\right)$ satisfies

$$
\begin{equation*}
\beta_{2 *}=\beta_{0}-\frac{d_{\beta_{0}}\left(\beta_{*}-\beta_{0}\right)}{d_{\beta_{0}}+2 r_{\beta_{0}}\left(\beta_{*}-\beta_{0}\right)} \text { and } \lambda_{2}=\lambda \frac{\left(d_{\beta_{0}}+2 r_{\beta_{0}}\left(\beta_{*}-\beta_{0}\right)\right)^{2}}{d_{\beta_{0}}^{2}}, \tag{6.3}
\end{equation*}
$$

where $r_{\beta_{0}}:=e_{1}^{\prime} \Omega^{-1} a_{0} \cdot\left(a_{0}^{\prime} \Omega^{-1} a_{0}\right)^{-1 / 2}$, see (4.2) of AMS. We let $\operatorname{POIS2}\left(Q ; \beta_{0}, \beta_{*}, \lambda\right)$ denote the optimal average-power test statistic for testing $\beta=\beta_{0}$ against $\left(\beta_{*}, \lambda\right)$ and ( $\beta_{2 *}, \lambda_{2}$ ). Its conditional critical value is denoted by $\kappa_{2, \beta_{0}}\left(Q_{T}\right)$. For brevity, the formulas for $\operatorname{POIS} 2\left(Q ; \beta_{0}, \beta_{*}, \lambda\right)$ and $\kappa_{2, \beta_{0}}\left(Q_{T}\right)$ are given in Section 17 in the SM.

The limit as $\beta_{0} \rightarrow \pm \infty$ of the $\operatorname{POIS} 2\left(Q ; \beta_{0}, \beta_{*}, \lambda\right)$ statistic is shown in (17.6) in the SM to be

$$
\begin{align*}
\operatorname{POIS} 2\left(Q ; \infty,\left|\rho_{u v}\right|, \lambda_{v}\right) & :=\frac{\psi\left(Q ; \rho_{u v}, \lambda_{v}\right)+\psi\left(Q ;-\rho_{u v}, \lambda_{v}\right)}{2 \psi_{2}\left(Q_{T} ;\left|\rho_{u v}\right|, \lambda_{v}\right)}, \text { where } \\
\psi\left(Q ; \rho_{u v}, \lambda_{v}\right) & :=\exp \left(-\lambda_{v}\left(1+r_{u v}^{2}\right) / 2\right)\left(\lambda_{v} \xi\left(Q ; \rho_{u v}\right)\right)^{-(k-2) / 4} I_{(k-2) / 2}\left(\sqrt{\lambda_{v} \xi\left(Q ; \rho_{u v}\right)}\right) \\
\psi_{2}\left(Q_{T} ;\left|\rho_{u v}\right|, \lambda_{v}\right) & :=\exp \left(-\lambda_{v} r_{u v}^{2} / 2\right)\left(\lambda_{v} r_{u v}^{2} Q_{T}\right)^{-(k-2) / 4} I_{(k-2) / 2}\left(\sqrt{\lambda_{v} r_{u v}^{2} Q_{T}}\right), \text { and } \\
\xi\left(Q ; \rho_{u v}\right) & :=Q_{S}+2 r_{u v} Q_{S T}+r_{u v}^{2} Q_{T}, \tag{6.4}
\end{align*}
$$

where $Q, Q_{S}, Q_{S T}$, and $Q_{T}$ are defined in (3.1), $\rho_{u v}$ is defined in (5.5), $r_{u v}$ and $\lambda_{v}$ are defined in (6.1), and $I_{\nu}(\cdot)$ denotes the modified Bessel function of the first kind of order $\nu$ (e.g., see Comment (ii) to Lemma 3 of AMS for more details regarding $\left.I_{\nu}(\cdot)\right)$.

Let $\kappa_{2, \infty}\left(q_{T}\right)$ denote the conditional critical value of the $\operatorname{POIS2}\left(Q ; \infty,\left|\rho_{u v}\right|, \lambda_{v}\right)$ test statistic. That is, $\kappa_{2, \infty}\left(q_{T}\right)$ is defined to satisfy

$$
\begin{equation*}
P_{Q_{1} \mid Q_{T}}\left(\operatorname{POIS} 2\left(Q ; \infty,\left|\rho_{u v}\right|, \lambda_{v}\right)>\kappa_{2, \infty}\left(q_{T}\right) \mid q_{T}\right)=\alpha \tag{6.5}
\end{equation*}
$$

for all $q_{T} \geq 0$, where $P_{Q_{1} \mid Q_{T}}\left(\cdot \mid q_{T}\right)$ denotes probability under the null density $f_{Q_{1} \mid Q_{T}}\left(\cdot \mid q_{T}\right)$, which is specified explicitly in (12.3) in the SM and does not depend on $\beta_{0}$.

When $\rho_{u v}=0$, the test based on $\operatorname{POIS2}\left(Q ; \infty,\left|\rho_{u v}\right|, \lambda_{v}\right)$ is the AR test. This follows because $\xi(Q ; 0)=Q_{S}, \psi\left(Q ; 0, \lambda_{v}\right)$ is monotone increasing in $\xi(Q ; 0)$, and $\psi_{2}\left(Q_{T} ; 0, \lambda_{v}\right)$ is a constant. Some intuition for this is that $E Q_{S T}=0$ under the null and $\lim _{\left|\beta_{0}\right| \rightarrow \infty} E Q_{S T}=0$ under any fixed
alternative $\beta_{*}$ when $\rho_{u v}=0.5$ In consequence, $Q_{S T}$ is not useful for distinguishing between $H_{0}$ and $H_{1}$ when $\left|\beta_{0}\right| \rightarrow \infty$ and $\rho_{u v}=0$. Furthermore, it is shown in (13.5) and Theorem 13.1 in the SM that the AR test is also the best one-sided test as $\beta_{0} \rightarrow+\infty$ and as $\beta_{0} \rightarrow-\infty$.

The following theorem shows that the $\operatorname{POIS2}\left(Q ; \infty,\left|\rho_{u v}\right|, \lambda_{v}\right)$ test provides a two-point averagepower bound as $\beta_{0} \rightarrow \pm \infty$ for any invariant similar test for any fixed $\left(\beta_{*}, \lambda\right)$ and $\Omega$.

Theorem 6.2 Let $\left\{\phi_{\beta_{0}}(Q): \beta_{0} \rightarrow \pm \infty\right\}$ be any sequence of invariant similar level $\alpha$ tests of $H_{0}: \beta=\beta_{0}$ for fixed known $\Omega$. For fixed $\left(\beta_{*}, \lambda\right),\left(\beta_{2 *}, \lambda_{2}\right)$ defined (6.3), and $\Omega$, the two-sided AE power envelope test POIS2 $\left(Q ; \infty,\left|\rho_{u v}\right|, \lambda_{v}\right)$ defined in (6.4) and (6.5) satisfies

$$
\begin{aligned}
& \limsup _{\beta_{0} \rightarrow \pm \infty}\left(P_{\beta_{*}, \beta_{0}, \lambda, \Omega}\left(\phi_{\beta_{0}}(Q)=1\right)+P_{\beta_{2 *}, \beta_{0}, \lambda_{2}, \Omega}\left(\phi_{\beta_{0}}(Q)=1\right)\right) / 2 \\
\leq & P_{\rho_{u v}, \lambda_{v}}\left(\operatorname{POIS} 2\left(Q ; \infty,\left|\rho_{u v}\right|, \lambda_{v}\right)>\kappa_{2, \infty}\left(Q_{T}\right)\right) \\
= & P_{-\rho_{u v}, \lambda_{v}}\left(\operatorname{POIS} 2\left(Q ; \infty,\left|\rho_{u v}\right|, \lambda_{v}\right)>\kappa_{2, \infty}\left(Q_{T}\right)\right) .
\end{aligned}
$$

Comments. (i). The power bound in Theorem 6.2 only depends on $\left(\beta_{*}, \lambda\right),\left(\beta_{2 *}, \lambda_{2}\right)$, and $\Omega$ through $\left|\rho_{u v}\right|$, which is the absolute magnitude of endogeneity under $\beta_{*}$, and $\lambda_{v}$, which is the concentration parameter.
(ii). The power bound in Theorem 6.2 is strictly less than one. Hence, it is informative.
(iii). For sign and rotation invariant similar tests $\phi_{\beta_{0}}(Q)$, the lim sup on the left-hand side in Theorem 6.2 is the average of two equal quantities.
(iv). Theorem 6.2 can be extended to cover sequences of similar tests $\left\{\phi_{\beta_{0}}(S, T): \beta_{0} \rightarrow\right.$ $\pm \infty\}$ that satisfy no invariance properties, using the proof of Theorem 1 in CHJ. In this case, the left-hand side (lhs) probabilities in Theorem 6.2 depend on $\pi$ or, equivalently ( $\lambda, \mu_{\pi} /\left\|\mu_{\pi}\right\|$ ), rather than just $\lambda$. In this case, Theorem 6.2 holds with $P_{\beta_{*}, \beta_{0}, \lambda, \Omega}\left(\phi_{\beta_{0}}(Q)=1\right)$ replaced by $\int P_{\beta_{*}, \lambda, \mu_{\pi} /\left\|\mu_{\pi}\right\|, \Omega}\left(\phi_{\beta_{0}}(S, T)=1\right) d U n i f\left(\mu_{\pi} /\left\|\mu_{\pi}\right\|\right)$ and analogously for the term that depends on $\left(\beta_{2 *}, \lambda_{2}\right)$, where $P_{\beta_{*}, \lambda, \mu_{\pi} /\left\|\mu_{\pi}\right\|, \Omega}(\cdot)$ denotes probability under $\left(\beta_{*}, \lambda, \mu_{\pi} /\left\|\mu_{\pi}\right\|, \Omega\right)$ and Unif( $\cdot$ ) denotes the uniform measure on the unit sphere in $R^{k}$.

### 6.3 Lower Bound on the Probability That a CS Has Infinite Length

Next, we combine Theorems 5.1 and 6.2 to provide a lower bound on the probability that a sign and rotation invariant similar CS has infinite length. The same lower bound applies to the average probability over $\left(\beta_{*}, \lambda\right)$ and $\left(\beta_{2 *}, \lambda\right)$ that a rotation invariant similar CS has right (left)

[^5]infinite length. For a similar CS with no invariance properties, the same lower bound applies to a different average probability that the CS has right (left) infinite length.

Let $P_{\beta_{*}, \lambda, \Omega}(\cdot)$ denote probability for events determined by $\left(Z^{\prime} Z\right)^{1 / 2} Z^{\prime} Y$ that depend on $\pi$ only through $\lambda$, such as events that are determined by a CS based on invariant tests.

Corollary 6.3 Suppose $C S_{\phi}(Y)$ is a CS based on invariant similar level $\alpha$ tests $\phi\left(Q_{\beta_{0}}(Y)\right)$ that satisfy the continuity condition in Theorem 5.1. (a) For any fixed $\left(\beta_{*}, \lambda, \Omega\right)$,

$$
\begin{aligned}
& \left(P_{\beta_{*}, \lambda, \Omega}\left(R \operatorname{Length}\left(C S_{\phi}(Y)\right)=\infty\right)+P_{\beta_{2 *}, \lambda_{2}, \Omega}\left(R \operatorname{Length}\left(C S_{\phi}(Y)\right)=\infty\right)\right) / 2 \\
\geq & 1-P_{\rho_{u v}, \lambda_{v}}\left(\operatorname{POIS} 2\left(Q ; \infty,\left|\rho_{u v}\right|, \lambda_{v}\right)>\kappa_{2, \infty}\left(Q_{T}\right)\right) \text { and } \\
& \left(P_{\beta_{*}, \lambda, \Omega}\left(\operatorname{Length}\left(C S_{\phi}(Y)\right)=\infty\right)+P_{\beta_{2 *}, \lambda_{2}, \Omega}\left(\operatorname{Length}\left(C S_{\phi}(Y)\right)=\infty\right)\right. \\
\geq & 1-P_{\rho_{u v}, \lambda_{v}}\left(\operatorname{POIS} 2\left(Q ; \infty,\left|\rho_{u v}\right|, \lambda_{v}\right)>\kappa_{2, \infty}\left(Q_{T}\right)\right) .
\end{aligned}
$$

(b) If the tests $\phi\left(Q_{\beta_{0}}(Y)\right)$ also are sign invariant, then for any fixed $\left(\beta_{*}, \lambda, \Omega\right)$,

$$
P_{\beta_{*}, \pi, \Omega}\left(\operatorname{Length}\left(C S_{\phi}(Y)\right)=\infty\right) \geq 1-P_{\rho_{u v}, \lambda_{v}}\left(\operatorname{POIS} 2\left(Q ; \infty,\left|\rho_{u v}\right|, \lambda_{v}\right)>\kappa_{2, \infty}\left(Q_{T}\right)\right) .
$$

Comments. (i). All three lower bounds in Corollary 6.3 are the same. The different parts of Corollary 6.3 specify different probabilities or average probabilities that have this lower bound.
(ii). Corollary 6.3(a) also holds for a similar CS that does not satisfy any invariance properties.

In this case, $P_{\beta_{*}, \lambda, \Omega}\left(R \operatorname{Length}\left(C S_{\phi}(Y)\right)=\infty\right)$ is replaced by $\int P_{\beta_{*}, \lambda, \mu_{\pi} /\left\|\mu_{\pi}\right\|, \Omega}\left(R \operatorname{Length}\left(C S_{\phi}(Y)\right)=\right.$ $\infty) d U n i f\left(\mu_{\pi} /\left\|\mu_{\pi}\right\|\right)$ and analogously for the other three lhs terms that depend on $\operatorname{LLength}\left(\operatorname{CS}_{\phi}(Y)\right)$ and/or $\left(\beta_{2 *}, \lambda_{2}\right)$. This holds provided the similar level $\alpha$ tests $\phi\left(S_{\beta_{0}}(Y), T_{\beta_{0}}(Y)\right)$ that define the CS satisfy the conditions in Comment (iii) to Theorem 5.1.

### 6.4 Power of the AR, LM, and CLR Tests as $\boldsymbol{\beta}_{0} \rightarrow \pm \infty$

Here, we provide the power of the AR, LM, and CLR tests as $\beta_{0} \rightarrow \pm \infty$ for fixed $\left(\beta_{*}, \Omega\right)$.
Theorem 6.4 For fixed true $\left(\beta_{*}, \lambda, \Omega\right)$, the AR, LM, and CLR tests satisfy
(a) $\lim _{\beta_{0} \rightarrow \pm \infty} P_{\beta_{*}, \beta_{0}, \lambda, \Omega}\left(A R>\chi_{k, 1-\alpha}^{2} / k\right)=P_{\rho_{u v}, \lambda_{v}}\left(A R>\chi_{k, 1-\alpha}^{2} / k\right)=P\left(\chi_{k}^{2}\left(\lambda_{v}\right)>\chi_{k, 1-\alpha}^{2}\right)$,
(b) $\lim _{\beta_{0} \rightarrow \pm \infty} P_{\beta_{*}, \beta_{0}, \lambda, \Omega}\left(L M>\chi_{1,1-\alpha}^{2}\right)=P_{\rho_{u v}, \lambda_{v}}\left(L M>\chi_{1,1-\alpha}^{2}\right)$, and
(c) $\lim _{\beta_{0} \rightarrow \pm \infty} P_{\beta_{*}, \beta_{0}, \lambda, \Omega}\left(L R>\kappa_{L R, \alpha}\left(Q_{T}\right)\right)=P_{\rho_{u v}, \lambda_{v}}\left(L R>\kappa_{L R, \alpha}\left(Q_{T}\right)\right)$,
where $A R, L M$, and $L R$ are defined as functions of $Q$ in 3.3, $\chi_{m, 1-\alpha}^{2}$ is the $1-\alpha$ quantile of the $\chi_{m}^{2}$ distribution, and $\chi_{m}^{2}\left(\lambda_{v}\right)$ is a noncentral $\chi_{m}^{2}$ random variable with noncentrality parameter $\lambda_{v}$.

Comments. (i) By Theorem 5.1(c), Theorem 6.4 provides the probabilities that the AR, LM, and CLR CS's have infinite length when the true parameters are $\left(\beta_{*}, \lambda, \Omega\right)$. These probabilities depend only on $\left(\left|\rho_{u v}\right|, \lambda_{v}\right)$. For the AR CS, they only depend on $\lambda_{v}$.
(ii) As pointed out by a referee, the AR CS has infinite length when the first-stage F test strictly fails to reject $H_{0}: \pi=0_{k}$, meaning that $y_{2}^{\prime} P_{Z} y_{2} / \omega_{2}<\chi_{k, 1-\alpha}^{2}$ (with a strict inequality). When the first-stage F test rejects $H_{0}: \pi=0_{k}$, i.e., $y_{2}^{\prime} P_{Z y_{2}} / \omega_{2}>\chi_{k, 1-\alpha}^{2}$, the AR CS has finite length. When $y_{2}^{\prime} P_{Z} y_{2} / \omega_{2}=\chi_{k, 1-\alpha}^{2}$, the AR CS can have infinite length, right length, or left length, or have finite length ${ }^{6}$ Results in Mikusheva (2010, Proofs of Thms. 1 and 2) provide expressions for the cases where the LM and CLR CS's have infinite lengths, but they do not seem to have as simple intuitive interpretations as for the AR CS.

## 7 Comparisons of Probabilities That Confidence Sets Have Infinite Length

Next, we investigate how close are the probabilities the CLR CS has infinite length to the lower bound in Corollary 6.3. Let POIS2 refer to the tests that generates the two-sided AE power envelope of AMS. These tests depend on the alternative $\left(\beta_{*}, \lambda\right)$ considered and $\Omega$. Let POIS2 $\infty_{\infty}$ refer to the tests in (6.4), which are the limits as $\beta_{0} \rightarrow \pm \infty$ of the POIS2 tests. These tests depend on $\beta_{*}$ (through $\left|\rho_{u v}\right|$ ) and $\lambda_{v}$. Let POIS2 and POIS $2_{\infty}$ CS's refer to the CS's constructed by inverting the POIS2 and POIS2 $\infty_{\infty}$ tests. These CS's are infeasible because they depend on knowing $\left(\beta_{*}, \lambda\right)$.

Table I reports differences in simulated probabilities that the CLR and POIS2 $\infty_{\infty}$ CS's have infinite lengths. The latter provide a lower bound on infinite-length probabilities for CS's based on sign and rotation invariant tests, such as the CLR CS, by Corollary 6.3(b). Hence, these differences are necessarily nonnegative. The results cover $k=2,5,10,20,40$, a range of $\lambda$ values between 1 and 60 depending on the value of $k$, and $\rho_{u v}=0, .3, .5, .7, .9$. Table I also reports the probabilities that the CLR CS has infinite length for the same $k$ and $\lambda$ values and a subset of the $\rho_{u v}$ values, viz., $0, .7, .9$. The true value of $\beta_{*}$ is taken to be 0 wlog by Section 22 in the SM. The results for negative and positive $\rho_{u v}$ values are the same by Section 22 in the SM, and hence, results for negative $\rho_{u v}$ are not reported. The number of simulation repetitions employed is 50,000 . The critical values are determined using 100,000 simulation repetitions.

The results show that the CLR CS is not close to optimal in some parameter scenarios. In

[^6]particular, the differences in probabilities of infinite length (DPIL's) between the CLR and the POIS $2_{\infty}$ CS's are positive for numerous combinations of $\left(k, \lambda, \rho_{u v}\right)$. The DPIL's are increasing in $k$, decreasing in $\left|\rho_{u v}\right|$, and maximized in the middle of the range of $\lambda$ values considered. For example, for $\left(k, \rho_{u v}\right)=(2,0)$, DPIL $\in[.002, .016]$ over the $\lambda$ values considered, whereas for $\left(k, \rho_{u v}\right)=(5,0)$, DPIL $\in[.003, .031]$ and for $\left(k, \rho_{u v}\right)=(40,0)$, DPIL $\in[.002, .049] .7$ Hence, $k$ has a noticeable effect on the magnitude of non-optimality of the CLR CS with larger values of $k$ leading to larger nonoptimality. For $(k, \lambda)=(5,10)$, we have DPIL $\in[.002, .031]$ over the $\rho_{u v}$ values considered, and for $(k, \lambda)=(20,15)$, we have DPIL $\in[.001, .046]$ over the $\rho_{u v}$ values considered. Hence, $\left|\rho_{u v}\right|$ also has a noticeable effect on the magnitude of non-optimality of the CLR CS in terms of DPIL's with non-optimality greatest at $\rho_{u v}=0.8$

## 8 Optimality of CLR and LM Tests as $\rho_{\mathrm{uv}} \rightarrow \pm 1$ or $\rho_{\Omega} \rightarrow \pm 1$

The results of Table I show that the magnitude of non-optimality of the CLR CS decreases as $\left|\rho_{u v}\right|$ increases to 1 . This raises the question of whether CLR tests are optimal in some sense in the limit as $\left|\rho_{u v}\right| \rightarrow 1$. In this section, we show that this is indeed the case, not just for power as $\beta_{0} \rightarrow \pm \infty$, but uniformly over all $\left(\beta_{0}, \beta_{*}\right)$ parameter values in a two-sided AE power sense.

Let $\rho_{\Omega}$ denote the correlation parameter corresponding to the reduced-form variance matrix $\Omega$, i.e., $\rho_{\Omega}:=\omega_{12} /\left(\omega_{1} \omega_{2}\right)$.

In this section, we provide parameter configurations under which the CLR and LM tests have optimality properties. The results cover the case of strong and semi-strong identification (where $\lambda \rightarrow \infty$ ). They cover the cases where $\rho_{u v} \rightarrow \pm 1$ or $\rho_{\Omega} \rightarrow \pm 1$ for (almost) any fixed values of the other parameters, which includes weak identification of any strength. And, they cover the cases where $\left(\rho_{u v}, \beta_{0}\right) \rightarrow( \pm 1, \pm \infty)$ or $\left(\rho_{\Omega}, \beta_{0}\right) \rightarrow( \pm 1, \pm \infty)$ and the other parameters are fixed at (almost) any values, which also includes weak identification.

In somewhat related results, CHJ show that the CLR and LM tests can be written as the limits of certain WAP LR tests, which indicates that they are at least close to being admissible.

Let $d_{\beta_{*}}^{2}:=d_{\beta_{*}}^{2}\left(\beta_{0}, \Omega\right)$ and $c_{\beta_{*}}^{2}:=c_{\beta_{*}}^{2}\left(\beta_{0}, \Omega\right)$. As in Section 6.2, let $\operatorname{POIS} 2\left(Q ; \beta_{0}, \beta_{*}, \lambda\right)$ and $\kappa_{2, \beta_{0}}\left(Q_{T}\right)$ denote the optimal average-power test statistic and its data-dependent critical value. Let $\chi_{1}^{2}\left(c_{\infty}^{2}\right)$ denote a noncentral $\chi_{1}^{2}$ random variable with noncentrality parameter $c_{\infty}^{2}$.

[^7]Theorem 8.1 Consider any sequence of null parameters $\beta_{0}$ and true parameters $\left(\beta_{*}, \lambda, \Omega\right)$ such that $\lambda d_{\beta_{*}}^{2} \rightarrow \infty$ and $\lambda^{1 / 2} c_{\beta_{*}} \rightarrow c_{\infty} \in R \backslash\{0\}$. Then, as $\lambda d_{\beta_{*}}^{2} \rightarrow \infty$ and $\lambda^{1 / 2} c_{\beta_{*}} \rightarrow c_{\infty}$,
(a) $P_{\beta_{*}, \beta_{0}, \lambda, \Omega}\left(\operatorname{POIS} 2\left(Q ; \beta_{0}, \beta_{*}, \lambda\right)>\kappa_{2, \beta_{0}}\left(Q_{T}\right)\right) \rightarrow P\left(\chi_{1}^{2}\left(c_{\infty}^{2}\right)>\chi_{1,1-\alpha}^{2}\right)$,
(b) $P_{\beta_{*}, \beta_{0}, \lambda, \Omega}\left(L R>\kappa_{L R, \alpha}\left(Q_{T}\right)\right) \rightarrow P\left(\chi_{1}^{2}\left(c_{\infty}^{2}\right)>\chi_{1,1-\alpha}^{2}\right)$, and
(c) $P_{\beta_{*}, \beta_{0}, \lambda, \Omega}\left(L M>\chi_{1,1-\alpha}^{2}\right) \rightarrow P\left(\chi_{1}^{2}\left(c_{\infty}^{2}\right)>\chi_{1,1-\alpha}^{2}\right)$.

Comments. (i). Theorem 8.1 shows that the CLR and LM tests have the same limit power as the POIS2 test. Theorem 8.1 provides both finite-sample limiting optimality results, where $n$ is fixed and the limits are determined by sequences of parameters $\left(\beta_{0}, \beta_{*}, \lambda, \Omega\right)$, and large-sample limiting optimality results, where the limits are determined by sequences of sample sizes $n$ and parameters $\left(\beta_{0}, \beta_{*}, \lambda, \Omega\right)$.
(ii). By Corollary 1 of AMS, for any invariant similar test $\phi(Q)$, for any $\left(\beta_{*}, \beta_{0}, \lambda, \Omega\right)$,

$$
\begin{equation*}
\frac{1}{2}\left(P_{\beta_{*}, \beta_{0}, \lambda, \Omega}(\phi(Q)=1)+P_{\beta_{2 *}, \beta_{0}, \lambda_{2}, \Omega}(\phi(Q)=1)\right) \leq P_{\beta_{*}, \beta_{0}, \lambda, \Omega}\left(\operatorname{POIS} 2\left(Q ; \beta_{0}, \beta_{*}, \lambda\right)>\kappa_{2, \beta_{0}}\left(Q_{T}\right)\right) \tag{8.1}
\end{equation*}
$$

That is, the POIS2 test determines the two-sided AE average power envelope of AMS for invariant similar tests, where the average is over $\left(\beta_{*}, \lambda\right)$ and $\left(\beta_{2 *}, \lambda_{2}\right)$. A fortiori, by Theorem 1 of CHJ, for any similar test $\phi([S: T])$ (that is not necessarily invariant), for any $\left(\beta_{*}, \beta_{0}, \lambda, \Omega\right)$, 8.1) holds with $P_{\beta_{*}, \beta_{0}, \lambda, \Omega}(\phi(Q)=1)$ replaced by the power average $\int P_{\beta_{*}, \beta_{0}, \lambda, \mu_{\pi} /\left\|\mu_{\pi}\right\|, \Omega}(\phi([S: T])=$ 1) $d U n i f\left(\mu_{\pi} /\left\|\mu_{\pi}\right\|\right)$ and likewise for the second lhs summand in 8.1). Hence, the POIS2 test also determines this average power envelope for similar tests.

These results and Theorem 8.1 show that the CLR and LM tests achieve these average power envelopes for all $\left(\beta_{*}, \beta_{0}, \lambda, \Omega\right)$ asymptotically when $\lambda d_{\beta_{*}}^{2} \rightarrow \infty$ and $\lambda^{1 / 2} c_{\beta_{*}} \rightarrow c_{\infty} \neq 0$.
(iii) The power envelopes in Comment (ii) translate immediately into false coverage probability (FCP) lower bounds for CS's based on invariant similar tests and similar tests. Specifically, one minus the lhs in (8.1), which equals the average FCP of the point $\beta_{0}$ by the CS based on $\phi(Q)$, where the average is over the truth being $\left(\beta_{*}, \lambda\right)$ and $\left(\beta_{2 *}, \lambda_{2}\right)$, is greater than or equal to one minus the rhs in 8.1]. In the case of non-invariant similar tests, the bound is on the average of the FCP's of the CS with averaging over $\left(\beta_{*}, \lambda\right)$ and $\left(\beta_{2 *}, \lambda_{2}\right)$ and $\mu_{\pi} /\left\|\mu_{\pi}\right\|$ in the unit sphere in $R^{k}$. Thus, Theorem 8.1 shows that the CLR and LM CS's have optimal average FCP properties asymptotically when $\lambda d_{\beta_{*}}^{2} \rightarrow \infty$ and $\lambda^{1 / 2} c_{\beta_{*}} \rightarrow c_{\infty} \neq 0$.
(iv). Theorem 8.1 does not apply when the IV's are completely irrelevant, i.e., $\lambda=0$, because $\lambda=0$ implies that $c_{\infty}=0$. However, Theorem 8.1 does cover some cases where the IV's can be arbitrarily weak, see Theorem 8.2 below.

Next, we provide conditions under which $\lambda d_{\beta_{*}}^{2} \rightarrow \infty$ and $\lambda^{1 / 2} c_{\beta_{*}} \rightarrow c_{\infty} \in R \backslash\{0\}$, as is assumed
in Theorem 8.1. First, if $\beta_{0}$ and $\Omega$ are fixed, $\Omega$ is nonsingular, and $\left(\beta_{*}, \lambda\right)$ satisfy $\lambda \rightarrow \infty$ and

$$
\begin{equation*}
\lambda^{1 / 2}\left(\beta_{*}-\beta_{0}\right) \rightarrow L \in R \text { as } \lambda \rightarrow \infty \tag{8.2}
\end{equation*}
$$

then $\lambda d_{\beta_{*}}^{2} \rightarrow \infty$ and $\lambda^{1 / 2} c_{\beta_{*}} \rightarrow c_{\infty} \in R \backslash\{0\}$ with $c_{\infty}=L\left(b_{0}^{\prime} \Omega b_{0}\right)^{-1 / 2}$. Here $L$ indexes the local alternatives against which the tests have nontrivial power. This result covers the usual strong IV case in which $\pi$ is fixed, $Z^{\prime} Z$ depends on $n$, and $\lambda=\pi^{\prime} Z^{\prime} Z \pi \rightarrow \infty$ as $n \rightarrow \infty$.

The scenario in (8.2) also covers cases where $\pi=\pi_{n} \rightarrow 0$ as $n \rightarrow \infty$, but sufficiently slowly that $\lambda=\pi_{n}^{\prime} Z^{\prime} Z \pi_{n} \rightarrow \infty$ as $n \rightarrow \infty$, which covers "semi-strong" identification. As far as we are aware, this is the only optimality property in the literature for tests under semi-strong identification. The scenario in (8.2) also covers finite-sample, i.e., fixed $n$, cases in which $Z^{\prime} Z$ is fixed, $\pi$ diverges, i.e., $\|\pi\| \rightarrow \infty$, and $\lambda_{\min }\left(Z^{\prime} Z\right)>0$. In these cases, $\lambda=\pi^{\prime} Z^{\prime} Z \pi \rightarrow \infty$ as $\|\pi\| \rightarrow \infty$.

The most novel cases in which Theorem 8.1 applies are when $\rho_{u v} \rightarrow \pm 1$ or $\rho_{\Omega} \rightarrow \pm 1$. The next result shows that $\lambda d_{\beta_{*}}^{2} \rightarrow \infty$ and $\lambda^{1 / 2} c_{\beta_{*}} \rightarrow c_{\infty} \in R \backslash\{0\}$ when $\rho_{u v} \rightarrow \pm 1$ or $\rho_{\Omega} \rightarrow \pm 1$ and the other parameters are fixed at (almost) any values. It also shows that this holds when ( $\left.\rho_{u v}, \beta_{0}\right) \rightarrow(1, \pm \infty)$ or $(-1, \pm \infty)$ or $\left(\rho_{\Omega}, \beta_{0}\right) \rightarrow(1, \pm \infty)$ or $(-1, \pm \infty)$ and the other parameters are fixed at (almost) any values.

Theorem 8.2 (a) Suppose the parameters $\beta_{0}, \beta_{*}, \sigma_{u}>0, \sigma_{v}>0$, and $\lambda>0$ are fixed, $\rho_{u v} \in$ $(-1,1)$, and $\rho_{u v} \rightarrow \pm 1$. Then, (i) $\lim _{\rho_{u v} \rightarrow \pm 1} \lambda^{1 / 2} c_{\beta_{*}}=\lambda^{1 / 2}\left(\beta_{*}-\beta_{0}\right) /\left|\sigma_{u} \pm\left(\beta_{*}-\beta_{0}\right) \sigma_{v}\right|$ and (ii) $\lim _{\rho_{u v} \rightarrow \pm 1} \lambda d_{\beta_{*}}^{2}=\infty$ provided $\beta_{*}-\beta_{0} \neq \mp \sigma_{u} / \sigma_{v}$.
(b) Suppose the parameters $\beta_{0}, \beta_{*}, \omega_{1}>0, \omega_{2}>0$, and $\lambda>0$ are fixed, $\rho_{\Omega} \in(-1,1)$, and $\rho_{\Omega} \rightarrow \pm 1$. Then, (i) $\lim _{\rho_{\Omega} \rightarrow \pm 1} \lambda^{1 / 2} c_{\beta_{*}}=\lambda^{1 / 2}\left(\beta_{*}-\beta_{0}\right) /\left|\omega_{1} \mp \omega_{2} \beta_{0}\right|$ provided $\beta_{0} \neq \pm \omega_{1} / \omega_{2}$ and (ii) $\lim _{\rho_{\Omega} \rightarrow \pm 1} \lambda d_{\beta_{*}}^{2}=\infty$ provided $\beta_{0} \neq \pm \omega_{1} / \omega_{2}$ and $\beta_{*} \neq \pm \omega_{1} / \omega_{2}$.
(c) Suppose the parameters are as in part (a) except $\left(\rho_{u v}, \beta_{0}\right) \rightarrow(1, \pm \infty)$ or $(-1, \pm \infty)$. Then, (i) $\lim _{\left(\rho_{u v}, \beta_{0}\right) \rightarrow(1, \pm \infty)} \lambda^{1 / 2} c_{\beta_{*}}=\lim _{\left(\rho_{u v}, \beta_{0}\right) \rightarrow(-1, \pm \infty)} \lambda^{1 / 2} c_{\beta_{*}}= \pm \lambda^{1 / 2} / \sigma_{v}$ and (ii) $\lim _{\left(\rho_{u v}, \beta_{0}\right) \rightarrow(1, \pm \infty)} \lambda d_{\beta_{*}}^{2}$ $=\lim _{\left(\rho_{u v}, \beta_{0}\right) \rightarrow(-1, \pm \infty)} \lambda d_{\beta_{*}}^{2}=\infty$.
(d) Suppose the parameters are as in part (b) except $\left(\rho_{\Omega}, \beta_{0}\right) \rightarrow(1, \pm \infty)$ or $(-1, \pm \infty)$. Then, (i) $\lim _{\left(\rho_{\Omega}, \beta_{0}\right) \rightarrow(1, \pm \infty)} \lambda^{1 / 2} c_{\beta_{*}}=\lim _{\left(\rho_{\Omega}, \beta_{0}\right) \rightarrow(-1, \pm \infty)} \lambda^{1 / 2} c_{\beta_{*}}=\mp \lambda^{1 / 2} / \omega_{2}$ and (ii) $\lim _{\left(\rho_{\Omega}, \beta_{0}\right) \rightarrow(1, \pm \infty)} \lambda d_{\beta_{*}}^{2}$ $=\infty$ provided $\beta_{*} \neq \omega_{1} / \omega_{2}$ and $\lim _{\left(\rho_{\Omega}, \beta_{0}\right) \rightarrow(-1, \pm \infty)} \lambda d_{\beta_{*}}^{2}=\infty$ provided $\beta_{*} \neq-\omega_{1} / \omega_{2}$.

Comments. (i). Combining Theorems 8.1 and 8.2 provides analytic finite-sample limiting optimality results for the CLR and LM tests and CS's as $\rho_{u v} \rightarrow \pm 1$ or $\rho_{\Omega} \rightarrow \pm 1$ with $\beta_{0}$ fixed or jointly with $\beta_{0} \rightarrow \pm \infty$ for (almost) any fixed values of the other parameters. These results apply for any strength of the IV's except $\lambda=0$. These results are much stronger than typical weighted average power (WAP) results because they hold for (almost) any fixed values of the parameters $\beta_{0}, \beta_{*}, \sigma_{1}$,
$\sigma_{v}$, and $\lambda>0$ when $\rho_{u v} \rightarrow \pm 1$ and (almost) any fixed values of the parameters $\beta_{0}, \beta_{*}, \omega_{1}, \omega_{2}$, and $\lambda>0$ when $\rho_{\Omega} \rightarrow \pm 1$.
(ii). The cases $\rho_{u v} \rightarrow \pm 1$ and $\rho_{\Omega} \rightarrow \pm 1$ are closely related because $\left(1-\rho_{\Omega}^{2}\right)^{1 / 2} \omega_{1}=\left(1-\rho_{u v}^{2}\right)^{1 / 2} \sigma_{u}$ by (16.10) in the SM. Thus, $\rho_{u v} \rightarrow \pm 1$ implies $\left|\rho_{\Omega}\right| \rightarrow 1$ and/or $\omega_{1} \rightarrow 0$. And, $\rho_{\Omega} \rightarrow \pm 1$ implies $\left|\rho_{u v}\right| \rightarrow 1$ and/or $\sigma_{u} \rightarrow 0$.
(iii) The asymptotic results of Theorem 8.2 as $\rho_{u v} \rightarrow \pm 1$ or $\rho_{\Omega} \rightarrow \pm 1$ are empirically relevant because they reflect the behavior of the CLR test even when $\left|\rho_{u v}\right|$ or $\left|\rho_{\Omega}\right|$ is not very close to one. See the results in Table I when $\rho_{u v}\left(=\rho_{\Omega}\right)$ equals .7 and .9. The results of Theorem 8.2 indicate that it would be informative for empirical papers to report estimates of $\rho_{\Omega}$ (which is consistently estimable even under weak IV's).

## 9 General Power/False-Coverage-Probability Comparisons

By Theorem 5.1, the results in Table I equal power differences (PD's) between the POIS2 and CLR tests as the null value $\beta_{0} \rightarrow \pm \infty$ for fixed true value $\beta_{*}=0$. Here, we consider PD's between the POIS2 and CLR tests for finite $\beta_{0}$ values, rather than PD's as $\beta_{0} \rightarrow \pm \infty$. Specifically, Table II reports maximum and average PD's over $\beta_{0} \in R$ and $\lambda>0$ for a fixed true value $\beta_{*}=0$ for a range of values of $\left(\rho_{u v}, k\right)$. As above, the choice of $\beta_{*}=0$ (and $\omega_{1}^{2}=\omega_{2}^{2}=1$ ) is wlog. These PD's are equivalent to false coverage probability differences (FCPD's) between the CLR and POIS2 CS's for a fixed true value $\beta_{*}$ at incorrect values $\beta_{0}$. They are necessarily nonnegative.

The $\lambda$ values considered are $1,3,5,7,10,15,20$, as well as 22,25 when $k=20$ and 40 , and $.7, .8, .9$ when $k=2$ and 5 and $\rho_{u v}=.9$. The positive and negative $\beta_{0}$ values considered are those with $\left|\beta_{0}\right| \in\{.25, .5, \ldots, 3.75,4,5,7.5,10,50,100,1000,10000\}$. These $\left(\lambda, \beta_{0}\right)$ values were chosen, based on preliminary simulations, to ensure that changes in the PD's in Table II (and Tables III and IV below) across neighboring values ( $\lambda, \beta_{0}$ ) are small.

The number of simulation repetitions employed is 5,000 . The critical values are determined using 100,000 simulation repetitions. For example, the simulation standard deviations for the PD's for $\left(\rho_{u v}, k\right)=(0,20)$ and any fixed $\left(\beta_{0}, \lambda\right)$ value range from $[.0013, .0040]$ across different $\left(\beta_{0}, \lambda\right)$ values, which compares to simulated averages of the PD's over $\left(\beta_{0}, \lambda\right)$ values that are of the . 014 order of magnitude.

Tables II(a) and II(b) contain the same numbers, but are reported differently to make the patterns in the table more clear. Table II(a) shows variation across $k$ for fixed $\rho_{u v}$, whereas Table II(b) shows variation across $\rho_{u v}$ for fixed $k$. The third and fourth columns in each table report the values of $\lambda$ and $\beta_{0}$ at which the maximum PD is obtained. The fifth column in each table reports
$\rho_{u v, 0}$, which is the correlation between the structural-equation and reduced-form errors when $\beta_{0}$ is the true value (based on the assumption that the consistently-estimable reduced-form variance matrix is the same whether the truth is $\beta_{0}$ or $\beta_{*}$ ). In contrast, $\rho_{u v}$ is the same correlation, but when $\beta_{*}$ is the true value - which is the true $\beta$ value in the PD simulations. The sixth column in the tables reports the power of the CLR test at the $\left(\beta_{0}, \lambda\right)$ values that maximize the PD for given $\left(\rho_{u v}, k\right)$, i.e., at $\left(\beta_{0, \max }, \lambda_{\max }\right)$.

Table II shows that the maximum (over $\left(\beta_{0}, \lambda\right)$ ) PD's between the POIS2 and CLR tests range between $[.016, .061]$ over the $\left(\rho_{u v}, k\right)$ values. On the other hand, the average (over $\left(\beta_{0}, \lambda\right)$ ) PD's only range between $[.002, .016]$ over the $\left(\rho_{u v}, k\right)$ values. This indicates that, although there are some $\left(\beta_{0}, \lambda\right)$ values at which the CLR test is noticeably off the two-sided AE power envelope, on average the CLR test's power is not far from the power envelope.

In contrast, the analogous maximum and average PD ranges for the AR test are [.079, .513] and $[.012, .179]$, see Table SM-III in the SM. For the LM test, they are [.242, .784] and [.010, .203], see Table SM-IV in the SM. Hence, the power of AR and LM tests is very much farther from the POIS2 power envelope than is the power of the CLR test.

Table II(a) shows that the maximum and average (over $\left(\beta_{0}, \lambda\right)$ ) PD's for the CLR test are clearly increasing in $k$. Table II(a) shows that for $\rho_{u v} \geq .3$, the PD's are maximized at more or less the same $\beta_{0}$ regardless of the value of $k$. For $\rho_{u v}=0$, this is also true to a certain extent, because the sign of $\beta_{0}$ is irrelevant (when $\rho_{u v}=0$ ) and the values 50 and 10,000 are both large values. Table II(a) also shows that for each $\rho_{u v}$, the PD's are maximized at $\lambda$ values that (weakly) increase with $k$. The increase is particularly evident going from $k=20$ to 40 .

Table II(b) shows that for $k \geq 5$, the maximum PD's are more or less the same for $\rho_{u v} \leq .7$, but noticeably lower for $\rho_{u v}=.9$. For $k=2$, the maximum PD's are more or less the same for all $\rho_{u v}$ considered. Table II(b) shows that, for each $k$, the PD's are maximized at $\left|\beta_{0}\right|$ values that are closer to 0 as $\rho_{u v}$ increases. Table II(b) also shows that, for each $k$, the PD's are maximized at $\lambda$ values that are closer to 0 as $\rho_{u v}$ increases?

In sum, the maximum PD's over $\left(\beta_{0}, \lambda\right)$ are found to increase in $k$ ceteris paribus and decrease in $\rho_{u v}$ ceteris paribus. The $\lambda$ values at which the maxima are obtained are found to (weakly) increase with $k$ ceteris paribus and decrease in $\rho_{u v}$ ceteris paribus. The $\left|\beta_{0}\right|$ values at which the maxima are obtained are found to be independent of $k$ ceteris paribus and decrease in $\rho_{u v}$ ceteris paribus.

Next, Figure 1 provides a picture of how the power of the CLR, AR, and POIS2 tests differ as a function of $\beta_{0}$ when other parameters are held fixed. Results given are for three parameter

[^8]configurations $\rho_{u v}=0, .5, .9$ with $\lambda=15, k=10$, and $\beta_{*}=0$ in all three configurations. These parameter configuations are chosen because they are ones in which the power of the CLR test is noticeably off the power envelope for sufficiently large $\beta_{0}$ when $\rho_{u v}=0$ and .5.

Figure 1(a) for $\rho_{u v}=0$ shows: (i) the power of all three tests does not go to one as $\beta_{0} \rightarrow \infty$ (the limit value depends on the magnitude of $\lambda$, which is 15 in Figure 1), (ii) the CLR test is off the power envelope and the AR test is on the power envelope (up to the numerical accuracy) for large $\beta_{0}-\beta_{*}$, and (iii) the reverse is true for smaller $\beta_{0}-\beta_{*}$.

Figures 1(b) for $\rho_{u v}=.5$ shows: (i) the power of all three tests does not go to one as $\beta_{0} \rightarrow \infty$, (ii) the CLR test is off the power envelope for large $\beta_{0}-\beta_{*}$ and on the power envelope (up to the numerical accuracy) for smaller $\beta_{0}-\beta_{*}$, and (iii) the AR test is on the power envelope (up to the numerical accuracy) for intermediate values of $\beta_{0}-\beta_{*}$ and off the power envelope for larger and smaller $\beta_{0}-\beta_{*}$.

Figures 1(c) for $\rho_{u v}=.9$ shows: (i) the power of all three tests does not go to one as $\beta_{0} \rightarrow \infty$, but the powers of the CLR and POIS2 tests are quite close to one for $\beta_{0}$ large, (ii) the CLR test is on the POIS2 power envelope (up to the numerical accuracy) for all $\beta_{0}$ values, and (iii) the AR test is off the POIS2 power envelope for most of the $\beta_{0}$ values considered, including small and large $\beta_{0}$ values.

In all of the simulations considered (across the parameters scenarios considered in Table II), the CLR test was found to be on the POIS2 power envelope (up to the numerical accuracy) for small values of $\beta_{0}-\beta_{*}$.

The numerical results in this section show that the finding of AMS that the CLR test is essentially on the two-sided AE power envelope does not hold when one considers a broader range of null and alternative hypothesis values $\left(\beta_{0}, \beta_{*}\right)$ than those considered in the numerical results in AMS.

## 10 Differences between CLR Power and an Average Over $\lambda$ Power Envelope

In this section, we introduce a "WAP2" power envelope for similar tests with weight functions over: (i) a finite grid of $\lambda$ values, $\left\{\lambda_{j}>0: j \leq J\right\}$, (ii) the same two-points ( $\beta_{*}, \lambda_{j}$ ) and ( $\beta_{2 *}, \lambda_{2 j}$ ) as in AMS for each $\lambda_{j}$ for $j \leq J$, and (iii) the same uniform weight function over $\mu_{\pi} /\left\|\mu_{\pi}\right\|$ as in CHJ. In particular, we use the uniform weight function over the 36 values of $\lambda$ in $\{2.5,5.0, \ldots, 90.0\}$.

The WAP2 envelope is a function of $\left(\beta_{0}, \beta_{*}\right)$. The $\operatorname{WAP} 2\left(Q, \beta_{0}, \beta_{*}\right)$ test statistic that generates this envelope is of the form $\sum_{j=1}^{J}\left(\psi\left(Q ; \beta_{0}, \beta_{* j}, \lambda_{j}\right)+\psi\left(Q ; \beta_{0}, \beta_{2 * j}, \lambda_{2 j}\right)\right) / \sum_{j=1}^{J} 2 \psi_{2}\left(Q_{T} ; \beta_{0}, \beta_{*}, \lambda_{j}\right)$, where the functions $\psi\left(Q ; \beta_{0}, \beta, \lambda\right)$ and $\psi_{2}\left(Q_{T} ; \beta_{0}, \beta, \lambda\right)$ are as in AMS (and as in 12.5) in the SM).

The $\operatorname{WAP} 2\left(Q, \beta_{0}, \beta_{*}\right)$ conditional critical value $\kappa_{2, \beta_{0}, J}\left(q_{T}\right)$ is defined to satisfy $P_{Q_{1} \mid Q_{T}}(W A P 2(Q$, $\left.\left.\beta_{0}, \beta_{*}\right)>\kappa_{2, \beta_{0}, J}\left(q_{T}\right) \mid q_{T}\right)=\alpha$ for all $q_{T} \geq 0$, where $P_{Q_{1} \mid Q_{T}}\left(\cdot \mid q_{T}\right)$ denotes probability under the density $f_{Q_{1} \mid Q_{T}}\left(\cdot \mid q_{T}\right)$, which is specified in 12.3) in the SM.

To be consistent with Tables I and II, we report PD's between the WAP2 $\left(Q, \beta_{0}, \beta_{*}\right)$ and CLR tests for $\beta_{*}=0$ and a range of $\beta_{0}$ values. These PD's are equivalent to the FCPD's between the CLR and WAP2 CS's for fixed true $\beta_{*}$ and varying incorrect $\beta_{0}$ values. The differences are necessarily nonnegative.

We consider $\rho_{u v} \in\{0, .3, .5, .7, .9, .95, .99\}, k=2,5,10,20,40$, the same $\beta_{0}$ values as in Table II, and $\omega_{1}^{2}=\omega_{2}^{2}=1$. (The large $\rho_{u v}$ values of .95 and .99 are included to show that the results are not sensitive to $\rho_{u v}$ being close to one.) Since $\beta_{*}=0, \rho_{\Omega}=\rho_{u v}$. Section 22 in the SM shows that taking $\beta_{*}=0$ and $\omega_{1}^{2}=\omega_{2}^{2}=1$ is wlog provided the support of the weight function for $\lambda$ is scaled by $\omega_{2}^{2}$ when $\omega_{2} \neq 1$. The number of simulation repetitions employed is 1,000 for each $\lambda_{j}$ value. With power averaged over the $36 \lambda_{j}$ values and independence of the simulation draws across $\lambda_{j}$, this yields simulation SD's that are comparable to using 36,000 simulation repetitions. The critical values are determined using 100,000 simulation repetitions for $k=5$ and 10,000 for other values of $k$.

For brevity, Table III reports results only for $k=5$ for a subset of the $\beta_{0}$ values considered. Results for all values of $k$ and $\beta_{0}$ considered are given in Table SM-V in the SM. Table IV reports summary results for all values of $k$. In particular, Table IV(a) provides the maxima over $\beta_{0}$ of the average over $\lambda$ PD's for each ( $\rho_{u v}, k$ ). Table IV(b) provides the average over $\beta_{0}$ of the average over $\lambda$ PD's for each $\left(\rho_{u v}, k\right)$.

Table III shows that the CLR test has power quite close to the WAP2 power envelope for $k=5$. The PD's for $\rho_{u v} \in\{0, .3, .5, .7\}$, we have $\mathrm{PD} \in[.000, .005]$ and $\mathrm{SD} \in[.0003, .0007]$ across all $\beta_{0}$ values. For $\rho_{u v} \in\{.9, .95, .99\}$, we have $\mathrm{PD} \in[.000, .001]$ and $\mathrm{SD} \in[.0000, .0003]$ across all $\beta_{0}$ values.

Table IV shows that PD's between the WAP2 power envelope and the CLR power are increasing in $k$ and decreasing in $\left|\rho_{u v}\right|$. For $k=2$, the maximum PD over $\beta_{0}$ and $\rho_{u v}$ values is very small: .004. In the worst case for CLR, which is when $\left(k, \rho_{u v}\right)=(40,0)$, the maximum PD over $\beta_{0}$ values is substantially larger: . 024 . The average (over $\beta_{0}$ values) PD in this case is .013 , which is not very large. For $k=40$ and $\rho_{u v} \geq .9$, the maximum PD (over $\beta_{0}$ and $\rho_{u v}$ values) is very small: .004. This is consistent with the theoretical optimality properties of the CLR test as $\rho_{u v} \rightarrow \pm 1$ described in Section 8. For $k=40$ and $\rho_{u v} \geq .9$, the average PD (over $\beta_{0}$ values and the five $\rho_{u v}$ values) is very small: . 000 . The second worst case for CLR in Table IV is when $\left(k, \rho_{u v}\right)=(20,0)$. In this case, the maximum PD over $\beta_{0}$ values is .013 , which is noticeably lower than .024 for $\left(k, \rho_{u v}\right)=(40,0)$.

In conclusion, the results in Tables III and IV show that the CLR test is very close to the WAP2
power envelope for most $\left(k, \rho_{u v}, \beta_{0}\right)$ values, but can deviate from it by as much as .024 for some $\beta_{0}$ values when $\left(k, \rho_{u v}\right)=(40,0)$.

## 11 Outline

References to sections, theorems, and lemmas with section numbers less than 11 refer to sections and results in the main paper.

Section 12 of this Supplemental Material (SM) provides expressions for the densities $f_{Q}\left(q ; \beta_{*}, \beta_{0}, \lambda, \Omega\right), f_{Q_{1} \mid Q_{T}}\left(q_{1} \mid q_{T}\right)$, and $f_{Q}\left(q ; \rho_{u v}, \lambda_{v}\right)$, expressions for the POIS2 test statistic and critical value of AMS, and expressions for the one-to-one transformations between the reducedform and structural variance matrices. Section 13 provides one-sided power bounds for invariant similar tests as $\beta_{0} \rightarrow \pm \infty$, where $\beta_{0}$ denotes the null hypothesis value. Section 14 corrects (4.1) of AMS, which concerns the two-point weight function that defines AMS's two-sided AE power envelope.

Section 15 proves Lemma 6.1. Section 16 proves Theorem 5.1 and its Comment (v). Section 17 proves Theorem 6.2 and its Comment (iv), Corollary 6.3 and its Comment (ii), and Theorem 6.4 . Section 18 proves Theorem 8.1. Section 19 proves Theorem 13.1 and Lemmas 14.1 and 14.2 .

Section 20 computes the structural error variance matrices in scenarios 1 and 2 considered in (4.2) and (4.3) in Section 4.

Section 21 shows how the model is transformed to go from a testing problem of $H_{0}: \beta=\beta_{0}$ versus $H_{1}: \beta=\beta_{*}$ for $\pi \in R^{k}$ and fixed $\Omega$ to a testing problem of $H_{0}: \bar{\beta}=0$ versus $H_{1}: \bar{\beta}=\bar{\beta}_{*}$ for some $\bar{\pi} \in R^{k}$ and some fixed $\bar{\Omega}$ with diagonal elements equal to one. This links the model considered here to the model used in the Andrews, Moreira, and Stock (2006) (AMS) numerical work.

Section 22 shows how the model is transformed to go from a testing problem of $H_{0}: \beta=\beta_{0}$ versus $H_{1}: \beta=\beta_{*}$ for $\pi \in R^{k}$ and fixed $\Omega$ to a testing problem of $H_{0}: \bar{\beta}=\bar{\beta}_{0}$ versus $H_{1}: \bar{\beta}=0$ for some $\bar{\pi} \in R^{k}$ and some fixed $\bar{\Omega}$ with diagonal elements equal to one. These transformation results imply that there is no loss in generality in the numerical results of the paper to taking $\omega_{1}^{2}=\omega_{2}^{2}=1$, $\beta_{*}=0$, and $\rho_{u v} \in[0,1]$ (rather than $\rho_{u v} \in[-1,1]$ ).

Section 23 provides numerical results that supplement the results given in Tables I-IV in the main paper.

Section 24 considers a variant of the CLR test, which we denote the CLR2 ${ }_{n}$ test, and computes probabilities that it has infinite length. It is not found to improve upon the CLR test.

Section 25 considers the linear IV model that allows for heteroskedasticity and autocorrelation (HC) in the errors, as in Moriera and Ridder (2017). It extends Theorem 5.1 to this model. Thus, it gives formulae for the probabilities that a CI has infinite right length, infinite left length, and infinite length in this model.

## 12 Definitions

### 12.1 Densities of Q when $\boldsymbol{\beta}=\boldsymbol{\beta}_{*}$ and when $\boldsymbol{\beta}_{0} \rightarrow \pm \infty$

In this subsection, we provide expressions for (i) the density $f_{Q}\left(q ; \beta_{*}, \beta_{0}, \lambda, \Omega\right)$ of $Q$ when the true value of $\beta$ is $\beta_{*}$, and the null value $\beta_{0}$ is finite, (ii) the conditional density $f_{Q_{1} \mid Q_{T}}\left(q_{1} \mid q_{T}\right)$ of $Q_{1}$ given $Q_{T}=q_{T}$, and (iii) the limit of $f_{Q}\left(q ; \beta_{*}, \beta_{0}, \lambda, \Omega\right)$ as $\beta_{0} \rightarrow \pm \infty$.

Let

$$
\begin{equation*}
\xi_{\beta_{*}}(q)=\xi_{\beta_{*}}\left(q ; \beta_{0}, \Omega\right):=c_{\beta_{*}}^{2} q_{S}+2 c_{\beta_{*}} d_{\beta_{*}} q_{S T}+d_{\beta_{*}}^{2} q_{T}, \tag{12.1}
\end{equation*}
$$

where $c_{\beta_{*}}=c_{\beta_{*}}\left(\beta_{0}, \Omega\right)$ and $d_{\beta_{*}}=d_{\beta_{*}}\left(\beta_{0}, \Omega\right)$. As in Section 6, $f_{Q}\left(q ; \beta_{*}, \beta_{0}, \lambda, \Omega\right)$ denotes the density of $Q:=[S: T]^{\prime}[S: T]$ when $[S: T]$ has the multivariate normal distribution in with $\beta=\beta_{*}$ and $\lambda=\mu_{\pi}^{\prime} \mu_{\pi}$. This noncentral Wishart density is

$$
\begin{gather*}
f_{Q}\left(q ; \beta_{*}, \beta_{0}, \lambda, \Omega\right)=K_{1} \exp \left(-\lambda\left(c_{\beta_{*}}^{2}+d_{\beta_{*}}^{2}\right) / 2\right) \operatorname{det}(q)^{(k-3) / 2} \exp \left(-\left(q_{S}+q_{T}\right) / 2\right) \\
\times\left(\lambda \xi_{\beta_{*}}(q)\right)^{-(k-2) / 4} I_{(k-2) / 2}\left(\sqrt{\lambda \xi_{\beta_{*}}(q)}\right), \text { where } \\
q=\left[\begin{array}{cc}
q_{S} & q_{S T} \\
q_{S T} & q_{T}
\end{array}\right], q_{1}=\binom{q_{S}}{q_{S T}} \in R^{+} \times R, q_{T} \in R^{+} \tag{12.2}
\end{gather*}
$$

$K_{1}^{-1}=2^{(k+2) / 2} p i^{1 / 2} \Gamma((k-1) / 2), I_{\nu}(\cdot)$ denotes the modified Bessel function of the first kind of order $\nu$, $p i=3.1415 \ldots$, and $\Gamma(\cdot)$ is the gamma function. This holds by Lemma 3(a) of AMS with $\beta=\beta_{*}$.

By Lemma 3(c) of AMS, the conditional density of $Q_{1}$ given $Q_{T}=q_{T}$ when $[S: T]$ is distributed as in (2.3) with $\beta=\beta_{0}$ is

$$
\begin{equation*}
f_{Q_{1} \mid Q_{T}}\left(q_{1} \mid q_{T}\right):=K_{1} K_{2}^{-1} \exp \left(-q_{S} / 2\right) \operatorname{det}(q)^{(k-3) / 2} q_{T}^{-(k-2) / 2} \tag{12.3}
\end{equation*}
$$

which does not depend on $\beta_{0}, \lambda$, or $\Omega$.
By Lemma 6.1, the limit of $f_{Q}\left(q ; \beta_{*}, \beta_{0}, \lambda, \Omega\right)$ as $\beta_{0} \rightarrow \pm \infty$ is the density $f_{Q}\left(q ; \rho_{u v}, \lambda_{v}\right)$. As in Section 6, $f_{Q}\left(q ; \rho_{u v}, \lambda_{v}\right)$ denotes the density of $Q:=[S: T]^{\prime}[S: T]$ when $[S: T]$ has a multivariate normal distribution with means matrix in 6.2 , all variances equal to one, and all covariances equal to zero. This is a noncentral Wishart density that has following form:

$$
\begin{align*}
f_{Q}\left(q ; \rho_{u v}, \lambda_{v}\right)= & K_{1} \exp \left(-\lambda_{v}\left(1+r_{u v}^{2}\right) / 2\right) \operatorname{det}(q)^{(k-3) / 2} \exp \left(-\left(q_{S}+q_{T}\right) / 2\right) \\
& \times\left(\lambda_{v} \xi\left(q ; \rho_{u v}\right)\right)^{-(k-2) / 4} I_{(k-2) / 2}\left(\sqrt{\lambda_{v} \xi\left(q ; \rho_{u v}\right)}\right), \text { where } \\
\xi\left(q ; \rho_{u v}\right):=q_{S}+ & 2 r_{u v} q_{S T}+r_{u v}^{2} q_{T} \tag{12.4}
\end{align*}
$$

This expression for the density holds by the proof of Lemma 3(a) of AMS with means matrix $\mu_{\pi} \cdot\left(1 / \sigma_{v}, r_{u v} / \sigma_{v}\right)$ in place of the means matrix $\mu_{\pi} \cdot\left(c_{\beta}, d_{\beta}\right)$.

### 12.2 POIS2 Test

Here we define the $\operatorname{POIS2}\left(q_{1}, q_{T} ; \beta_{0}, \beta_{*}, \lambda\right)$ test statistic of AMS, which is analyzed in Section 6. and its conditional critical value $\kappa_{2, \beta_{0}}\left(q_{T}\right)$.

Given $\left(\beta_{*}, \lambda\right)$, the parameters $\left(\beta_{2 *}, \lambda_{2}\right)$ are defined in (6.3), which is the same as (4.2) of AMS. By Cor. 1 of AMS, the optimal average-power test statistic against $\left(\beta_{*}, \lambda\right)$ and $\left(\beta_{2 *}, \lambda_{2}\right)$ is

$$
\begin{align*}
\operatorname{POIS} 2\left(Q ; \beta_{0}, \beta_{*}, \lambda\right) & :=\frac{\psi\left(Q ; \beta_{0}, \beta_{*}, \lambda\right)+\psi\left(Q ; \beta_{0}, \beta_{2 *}, \lambda_{2}\right)}{2 \psi_{2}\left(Q_{T} ; \beta_{0}, \beta_{*}, \lambda\right)}, \text { where } \\
\psi\left(Q ; \beta_{0}, \beta, \lambda\right) & :=\exp \left(-\lambda\left(c_{\beta}^{2}+d_{\beta}^{2}\right) / 2\right)\left(\lambda \xi_{\beta}(Q)\right)^{-(k-2) / 4} I_{(k-2) / 2}\left(\sqrt{\lambda \xi_{\beta}(Q)}\right), \\
\psi_{2}\left(Q_{T} ; \beta_{0}, \beta, \lambda\right) & :=\exp \left(-\lambda d_{\beta}^{2} / 2\right)\left(\lambda d_{\beta}^{2} Q_{T}\right)^{-(k-2) / 4} I_{(k-2) / 2}\left(\sqrt{\lambda d_{\beta}^{2} Q_{T}}\right), \tag{12.5}
\end{align*}
$$

$Q$ and $Q_{T}$ are defined in (3.1), $c_{\beta}=c_{\beta}(\beta, \Omega)$ and $d_{\beta}=d_{\beta}(\beta, \Omega)$ are defined in (2.3), $I_{\nu}(\cdot)$ is defined in 12.2$), \xi_{\beta}(Q)$ is defined in 12.1) with $Q$ and $\beta$ in place of $q$ and $\beta_{*}$, and $\lambda:=\mu_{\pi}^{\prime} \mu_{\pi}$. Note that $\psi_{2}\left(Q_{T} ; \beta_{*}, \lambda\right)=\psi_{2}\left(Q_{T} ; \beta_{2 *}, \lambda_{2}\right)$ by (6.3).

Let $\kappa_{2, \beta_{0}}\left(q_{T}\right)$ denote the conditional critical value of the $\operatorname{POIS} 2\left(Q ; \beta_{0}, \beta_{*}, \lambda\right)$ test statistic. That is, $\kappa_{2, \beta_{0}}\left(q_{T}\right)$ is defined to satisfy

$$
\begin{equation*}
P_{Q_{1} \mid Q_{T}}\left(\operatorname{POIS} 2\left(Q ; \beta_{0}, \beta_{*}, \lambda\right)>\kappa_{2, \beta_{0}}\left(q_{T}\right) \mid q_{T}\right)=\alpha \tag{12.6}
\end{equation*}
$$

for all $q_{T} \geq 0$, where $P_{Q_{1} \mid Q_{T}}\left(\cdot \mid q_{T}\right)$ denotes probability under the density $f_{Q_{1} \mid Q_{T}}\left(\cdot \mid q_{T}\right)$ defined in (12.3). The critical value function $\kappa_{2, \beta_{0}}(\cdot)$ depends on $\left(\beta_{0}, \beta_{*}, \lambda, \Omega\right)$ and $k$ (and $\left(\beta_{2 *}, \lambda_{2}\right)$ through $\left.\left(\beta_{*}, \lambda\right)\right)$.

### 12.3 Structural and Reduced-Form Variance Matrices

Let $u_{i}, v_{1 i}$, and $v_{2 i}$ denote the $i$ th elements of $u, v_{1}$, and $v_{2}$, respectively. We have

$$
v_{1 i}:=u_{i}+v_{2 i} \beta \text { and } \Omega=\left[\begin{array}{cc}
\omega_{1}^{2} & \omega_{12}  \tag{12.7}\\
\omega_{12} & \omega_{2}^{2}
\end{array}\right]
$$

where $\beta$ denotes the true value.
Given the true value $\beta$ and some structural error variance matrix $\Sigma$, the corresponding reduced-
form error variance matrix $\Omega(\beta, \Sigma)$ is

$$
\begin{align*}
\Omega(\beta, \Sigma) & :=\operatorname{Var}\left(\binom{v_{1 i}}{v_{2 i}}\right)=\operatorname{Var}\left(\binom{u_{i}+v_{2 i} \beta}{v_{2 i}}\right) \\
& =\left[\begin{array}{ll}
1 & \beta \\
0 & 1
\end{array}\right] \Sigma\left[\begin{array}{ll}
1 & 0 \\
\beta & 1
\end{array}\right]=\left[\begin{array}{cc}
\sigma_{u}^{2}+2 \sigma_{u v} \beta+\sigma_{v}^{2} \beta^{2} & \sigma_{u v}+\sigma_{v}^{2} \beta \\
\sigma_{u v}+\sigma_{v}^{2} \beta & \sigma_{v}^{2}
\end{array}\right], \text { where } \\
\Sigma & =\left[\begin{array}{cc}
\sigma_{u}^{2} & \sigma_{u v} \\
\sigma_{u v} & \sigma_{v}^{2}
\end{array}\right] . \tag{12.8}
\end{align*}
$$

Given the true value $\beta$ and the reduced-form error variance matrix $\Omega$, the structural variance matrix $\Sigma(\beta, \Omega)$ is

$$
\begin{align*}
\Sigma(\beta, \Omega) & :=\operatorname{Var}\left(\binom{u_{i}}{v_{2 i}}\right)=\operatorname{Var}\left(\binom{v_{1 i}-v_{2 i} \beta}{v_{2 i}}\right)  \tag{12.9}\\
& =\left[\begin{array}{cc}
1 & -\beta \\
0 & 1
\end{array}\right] \Omega\left[\begin{array}{cc}
1 & 0 \\
-\beta & 1
\end{array}\right]=\left[\begin{array}{cc}
\omega_{1}^{2}-2 \omega_{12} \beta+\omega_{2}^{2} \beta^{2} & \omega_{12}-\omega_{2}^{2} \beta \\
\omega_{12}-\omega_{2}^{2} \beta & \omega_{2}^{2}
\end{array}\right] .
\end{align*}
$$

Let $\sigma_{u}^{2}(\beta, \Omega), \sigma_{v}^{2}(\beta, \Omega)$, and $\sigma_{u v}(\beta, \Omega)$ denote the $(1,1),(2,2)$, and $(1,2)$ elements of $\Sigma(\beta, \Omega)$. Let $\rho_{u v}(\beta, \Omega)$ denote the correlation implied by $\Sigma(\beta, \Omega)$.

In the asymptotics as $\beta_{0} \rightarrow \pm \infty$, we fix $\beta_{*}$ and $\Omega$ and consider the testing problem as $\beta_{0} \rightarrow \pm \infty$. Rather than fixing $\Omega$, one can equivalently fix the structural variance matrix when $\beta=\beta_{*}$, say at $\Sigma_{*}$. Given $\beta_{*}$ and $\Sigma_{*}$, there is a unique reduced-form error variance matrix $\Omega=\Omega\left(\beta_{*}, \Sigma_{*}\right)$ defined using 12.8. Significant simplifications in certain formulae occur when they are expressed in terms of $\Sigma_{*}$, rather than $\Omega$, e.g., see Lemma 15.1 (e) below.

For notational simplicity, we denote the $(1,1),(2,2)$, and $(1,2)$ elements of $\Sigma_{*}$ by $\sigma_{u}^{2}, \sigma_{v}^{2}$, and $\sigma_{u v}$, respectively, without any $*$ subscripts. As defined in (5.5), $\rho_{u v}:=\sigma_{u v} /\left(\sigma_{u} \sigma_{v}\right)$. Thus, $\rho_{u v}$ is the correlation between the structural and reduced-form errors $u_{i}$ and $v_{2 i}$ when the true value of $\beta$ is $\beta_{*}$. Note that $\rho_{u v}$ does not change when $\left(\beta_{*}, \Sigma_{*}\right)$ is fixed (or, equivalently, $\left(\beta_{*}, \Omega\right)=\left(\beta_{*}, \Omega\left(\beta_{*}, \Sigma_{*}\right)\right)$ is fixed) and $\beta_{0}$ is changed. Also, note that $\sigma_{v}^{2}=\omega_{2}^{2}$ because both denote the variance of $v_{2 i}$ under $\beta=\beta_{*}$ and $\beta=\beta_{0}$.

## 13 One-Sided Power Bound as $\boldsymbol{\beta}_{0} \rightarrow \pm \infty$

In this section, we provide one-sided power bounds for invariant similar tests as $\beta_{0} \rightarrow \pm \infty$ for fixed $\beta_{*}$. The approach is the same as in Andrews, Moreira, and Stock (2004) (AMS04) except that
we consider $\beta_{0} \rightarrow \pm \infty$. Also see Mills, Moreira, and Vilela (2014).

### 13.1 Point Optimal Invariant Similar Tests for Fixed $\boldsymbol{\beta}_{0}$ and $\boldsymbol{\beta}_{*}$

First, we consider the point null and alternative hypotheses:

$$
\begin{equation*}
H_{0}: \beta=\beta_{0} \text { and } H_{1}: \beta=\beta_{*}, \tag{13.1}
\end{equation*}
$$

where $\pi \in R^{k}$ (or, equivalently, $\lambda \geq 0$ ) under $H_{0}$ and $H_{1}$.
Point optimal invariant similar (POIS) tests for any given null and alternative parameter values $\beta_{0}$ and $\beta_{*}$, respectively, and any given $\Omega$ are constructed in AMS04, Sec. 5. Surprisingly, the same test is found to be optimal for all values of $\pi$ under $H_{1}$, i.e., for all strengths of identification. The optimal test is constructed by determining the level $\alpha$ test that maximizes conditional power given $Q_{T}=q_{T}$ among tests that are invariant and have null rejection probability $\alpha$ conditional on $Q_{T}=q_{T}$, for each $q_{T} \in R$.

By AMS04 (Comment 2 to Cor. 2), the POIS test of $H_{0}: \beta=\beta_{0}$ versus $H_{1}: \beta=\beta_{*}$, for any $\pi \in R^{k}$ (or $\lambda \geq 0$ ) under $H_{1}$, rejects $H_{0}$ for large values of

$$
\begin{equation*}
\operatorname{POIS}\left(Q ; \beta_{0}, \beta_{*}\right):=Q_{S}+2 \frac{d_{\beta_{*}}\left(\beta_{0}, \Omega\right)}{c_{\beta_{*}}\left(\beta_{0}, \Omega\right)} Q_{S T} \tag{13.2}
\end{equation*}
$$

The critical value for the $\operatorname{POIS}\left(Q ; \beta_{0}, \beta_{*}\right)$ test is a conditional critical value given $Q_{T}=q_{T}$, which we denote by $\kappa_{\beta_{0}}\left(q_{T}\right)$. The critical value $\kappa_{\beta_{0}}\left(q_{T}\right)$ is defined to satisfy

$$
\begin{equation*}
P_{Q_{1} \mid Q_{T}}\left(\operatorname{POIS}\left(Q ; \beta_{0}, \beta_{*}\right)>\kappa_{\beta_{0}}\left(q_{T}\right) \mid q_{T}\right)=\alpha \tag{13.3}
\end{equation*}
$$

for all $q_{T} \geq 0$, where $P_{Q_{1} \mid Q_{T}}\left(\cdot \mid q_{T}\right)$ denotes probability under the conditional density $f_{Q_{1} \mid Q_{T}}\left(q_{1} \mid q_{T}\right)$ defined in 12.3). Although the density $f_{Q_{1} \mid Q_{T}}\left(q_{1} \mid q_{T}\right)$ does not depend on $\beta_{0}, \kappa_{\beta_{0}}\left(q_{T}\right)$ depends on $\beta_{0}$, as well as $\left(\beta_{*}, \Omega, k\right)$, because $\operatorname{POI} S\left(Q ; \beta_{0}, \beta_{*}\right)$ does.

Note that, although the same $\operatorname{POIS}\left(Q ; \beta_{0}, \beta_{*}\right)$ test is best for all strengths of identification, i.e., for all $\lambda=\mu_{\pi}^{\prime} \mu_{\pi}>0$, the power of this test depends on $\lambda$.

### 13.2 One-Sided Power Bound When $\boldsymbol{\beta}_{0} \rightarrow \pm \infty$

Now we consider the best one-sided invariant similar test as $\beta_{0} \rightarrow \pm \infty$ keeping ( $\beta_{*}, \Omega$ ) fixed. Lemma 15.1 below implies that

$$
\begin{equation*}
\lim _{\beta_{0} \rightarrow \pm \infty} \frac{d_{\beta_{*}}\left(\beta_{0}, \Omega\right)}{c_{\beta_{*}}\left(\beta_{0}, \Omega\right)}=\left(\mp \frac{\rho_{u v}}{\sigma_{v}\left(1-\rho_{u v}^{2}\right)^{1 / 2}}\right) /\left(\mp 1 / \sigma_{v}\right)=\frac{\rho_{u v}}{\left(1-\rho_{u v}^{2}\right)^{1 / 2}}, \tag{13.4}
\end{equation*}
$$

where $\rho_{u v}$, defined in (5.5), is the correlation between the structural and reduced-form errors $u_{i}$ and $v_{2 i}$ under $\beta_{*}$. Hence, the limit as $\beta_{0} \rightarrow \pm \infty$ of the $\operatorname{POIS}\left(Q ; \beta_{0}, \beta_{*}\right)$ test statistic in (13.2) is

$$
\begin{equation*}
\operatorname{POIS}\left(Q ; \infty, \rho_{u v}\right):=\lim _{\beta_{0} \rightarrow \pm \infty}\left(Q_{S}+2 \frac{d_{\beta_{*}}\left(\beta_{0}, \Omega\right)}{c_{\beta_{*}}\left(\beta_{0}, \Omega\right)} Q_{S T}\right)=Q_{S}+2 \frac{\rho_{u v}}{\left(1-\rho_{u v}^{2}\right)^{1 / 2}} Q_{S T} . \tag{13.5}
\end{equation*}
$$

Notice that (i) this limit is the same for $\beta_{0} \rightarrow+\infty$ and $\beta_{0} \rightarrow-\infty$, (ii) the $\operatorname{POIS}\left(Q ; \infty, \rho_{u v}\right)$ statistic depends on $\left(\beta_{*}, \Omega\right)=\left(\beta_{*}, \Omega\left(\beta_{*}, \Sigma_{*}\right)\right)$ only through $\rho_{u v}:=\operatorname{Corr}\left(\Sigma_{*}\right)$, and (iii) when $\rho_{u v}=0$, the $\operatorname{POIS}\left(Q ; \infty, \rho_{u v}\right)$ statistic is the AR statistic (times $k$ ). Some intuition for result (iii) is that $E Q_{S T}=0$ under the null and $\lim _{\left|\beta_{0}\right| \rightarrow \infty} E Q_{S T}=0$ under any fixed alternative $\beta_{*}$ when $\rho_{u v}=0$ (see the discussion in Section 6.2). In consequence, $Q_{S T}$ is not useful for distinguishing between $H_{0}$ and $H_{1}$ when $\left|\beta_{0}\right| \rightarrow \infty$ and $\rho_{u v}=0$.

Let $\kappa_{\infty}\left(q_{T}\right)$ denote the conditional critical value of the $\operatorname{POIS}\left(Q ; \infty, \rho_{u v}\right)$ test statistic. That is, $\kappa_{\infty}\left(q_{T}\right)$ is defined to satisfy

$$
\begin{equation*}
P_{Q_{1} \mid Q_{T}}\left(\operatorname{POIS}\left(Q ; \infty, \rho_{u v}\right)>\kappa_{\infty}\left(q_{T}\right) \mid q_{T}\right)=\alpha \tag{13.6}
\end{equation*}
$$

for all $q_{T} \geq 0$. The density $f_{Q_{1} \mid Q_{T}}\left(\cdot \mid q_{T}\right)$ of $P_{Q_{1} \mid Q_{T}}\left(\cdot \mid q_{T}\right)$ only depends on the number of IV's $k$, see (12.3). The critical value function $\kappa_{\infty}(\cdot)$ depends on $\rho_{u v}$ and $k$.

Let $\phi_{\beta_{0}}(Q)$ denote a test of $H_{0}: \beta=\beta_{0}$ versus $H_{1}: \beta=\beta_{*}$ based on $Q$ that rejects $H_{0}$ when $\phi_{\beta_{0}}(Q)=1$. In most cases, a test depends on $\beta_{0}$ because the distribution of $Q$ depends on $\beta_{0}$, see (2.3) and (3.1), and not because $\phi_{\beta_{0}}(\cdot)$ depends on $\beta_{0}$. For example, this is true of the AR, LM, and CLR tests in (3.3) and (3.4). However, we allow for dependence of $\phi_{\beta_{0}}(\cdot)$ on $\beta_{0}$ in the following result in order to cover all possible sequences of (non-randomized) tests of $H_{0}: \beta=\beta_{0}$.

Theorem 13.1 Let $\left\{\phi_{\beta_{0}}(Q): \beta_{0} \rightarrow \pm \infty\right\}$ be any sequence of invariant similar level $\alpha$ tests of $H_{0}: \beta=\beta_{0}$ versus $H_{1}: \beta=\beta_{*}$ when $Q$ has density $f_{Q}\left(q ; \beta, \beta_{0}, \lambda, \Omega\right)$ for some $\lambda \geq 0$ and $\Omega$ is fixed and known. For fixed true $\left(\beta_{*}, \lambda, \Omega\right)$, the $\operatorname{POIS}\left(Q ; \infty, \rho_{u v}\right)$ test satisfies

$$
\limsup _{\beta_{0} \rightarrow \pm \infty} P_{\beta_{*}, \beta_{0}, \lambda, \Omega}\left(\phi_{\beta_{0}}(Q)=1\right) \leq P_{\rho_{u v}, \lambda_{v}}\left(\operatorname{POIS}\left(Q ; \infty, \rho_{u v}\right)>\kappa_{\infty}\left(Q_{T}\right)\right) .
$$

Comments. (i). Theorem 13.1 shows that the $\operatorname{POIS}\left(Q ; \infty, \rho_{u v}\right)$ test provides an asymptotic power bound as $\beta_{0} \rightarrow \pm \infty$ for any invariant similar test for any fixed $\left(\beta_{*}, \lambda, \Omega\right)$. This power bound is strictly less than one. The reason is that $\lim _{\beta_{0} \rightarrow \pm \infty}\left|c_{\beta_{*}}\left(\beta_{0}, \Omega\right)\right| \nrightarrow \infty$. This is the same reason that the AR test does not have power that converges to one in this scenario, see Section 4. Hence, the bound in Theorem 13.1 is informative.
(ii). The power bound in Theorem 13.1 only depends on $\left(\beta_{*}, \lambda, \Omega\right)$ through $\rho_{u v}$, the magnitude
of endogeneity under $\beta_{*}$, and $\lambda_{v}$, the concentration parameter.
(iii). As an alternative to the power bound given in Theorem 13.1, one might consider developing a formal limit of experiments result, e.g., along the lines of van der Vaart (1998, Ch. 9). This approach does not appear to work for the sequence of experiments consisting of the two unconditional distributions of $[S: T]$ ( or $Q$ ) for $\beta=\beta_{0}, \beta_{*}$ and indexed by $\beta_{0}$ as $\beta_{0} \rightarrow \pm \infty$. The reason is that the likelihood ratio of these two distributions is asymptotically degenerate as $\beta_{0} \rightarrow \pm \infty$ (either 0 or $\infty$ depending on which density is in the numerator) when the truth is taken to be $\beta=\beta_{0}$. This occurs because the length of the mean vector of $T$ diverges to infinity as $\beta_{0} \rightarrow \pm \infty$ (provided $\lambda=\mu_{\pi}^{\prime} \mu_{\pi}>0$ ) by (2.3) and Lemma 15.1(c) below. For the sequence of conditional distributions of $Q$ given $Q_{T}=q_{T}$, it should be possible to obtain a formal limit of experiments result, but this would not very helpful because we are interested in the unconditional power of tests and a conditional limit of experiments result would not deliver this.
(iv). The proof of Theorem 13.1 is given in Section 19 below.

## 14 Equations (4.1) and (4.2) of AMS

This section corrects (4.1) of AMS, which concerns the two-point weight function that defines AMS's two-sided AE power envelope.

Equation (4.1) of AMS is: ${ }^{10}$ given $\left(\beta_{*}, \lambda\right)$, the second point $\left(\beta_{2 *}, \lambda_{2}\right)$ solves

$$
\begin{equation*}
\lambda_{2}^{1 / 2} c_{\beta_{2 *}}=-\lambda^{1 / 2} c_{\beta_{*}}(\neq 0) \text { and } \lambda_{2}^{1 / 2} d_{\beta_{2 *}}=\lambda^{1 / 2} d_{\beta_{*}} . \tag{14.1}
\end{equation*}
$$

AMS states that provided $\beta_{*} \neq \beta_{A R}$, the solutions to the two equations in (4.1) satisfy the two equations in (4.2) of AMS, which is the same as 6.3 ) and which we repeat here for convenience ${ }^{11}$

$$
\begin{align*}
& \beta_{2 *}=\beta_{0}-\frac{d_{\beta_{0}}\left(\beta_{*}-\beta_{0}\right)}{d_{\beta_{0}}+2 r_{\beta_{0}}\left(\beta_{*}-\beta_{0}\right)} \text { and } \lambda_{2}=\lambda \frac{\left(d_{\beta_{0}}+2 r_{\beta_{0}}\left(\beta_{*}-\beta_{0}\right)\right)^{2}}{d_{\beta_{0}}^{2}}, \text { where } \\
& r_{\beta_{0}}:=e_{1}^{\prime} \Omega^{-1} a_{0} \cdot\left(a_{0}^{\prime} \Omega^{-1} a_{0}\right)^{-1 / 2} \text { and } e_{1}:=(1,0)^{\prime} . \tag{14.2}
\end{align*}
$$

Equation (4.2) is correct as stated, but (4.1) of AMS is not correct. More specifically, it is not complete. It should be: given $\left(\beta_{*}, \lambda\right)$, the second point $\left(\beta_{2 *}, \lambda_{2}\right)$ solves either 14.1) or

$$
\begin{equation*}
\lambda_{2}^{1 / 2} c_{\beta_{2 *}}=\lambda^{1 / 2} c_{\beta_{*}}(\neq 0) \text { and } \lambda_{2}^{1 / 2} d_{\beta_{2 *}}=-\lambda^{1 / 2} d_{\beta_{*}} . \tag{14.3}
\end{equation*}
$$

[^9]For brevity, we write the "either or" conditions in (14.1) and (14.3) as

$$
\begin{equation*}
\lambda_{2}^{1 / 2} c_{\beta_{2 *}}=\mp \lambda^{1 / 2} c_{\beta_{*}}(\neq 0) \text { and } \lambda_{2}^{1 / 2} d_{\beta_{2 *}}= \pm \lambda^{1 / 2} d_{\beta_{*}} \tag{14.4}
\end{equation*}
$$

The reason (4.1) of AMS needs to be augmented by (14.3) is that for some $\left(\beta_{*}, \lambda\right)$, $\beta_{0}$, and $\Omega$, (4.1) has no real solutions $\left(\beta_{2 *}, \lambda_{2}\right)$ and the expressions for $\left(\beta_{2 *}, \lambda_{2}\right)$ in (4.2) of AMS do not satisfy (4.1). Once (4.1) of AMS is augmented by (14.3), there exist real solutions $\left(\beta_{2 *}, \lambda_{2}\right)$ to the augmented conditions and they are given by the expressions in (4.2) of AMS, i.e., by 14.2 ). This is established in the following lemma.

Lemma 14.1 The conditions in (14.4) hold iff the conditions in (4.2) of AMS hold, i.e., iff the conditions in 14.2 holds.

With (4.1) of AMS replaced by (14.4), the results in Theorem 8(b) and (c) of AMS hold as stated. That is, the two-point weight function that satisfies 14.4 leads to a two-sided weighted average power (WAP) test that is asymptotically efficient under strong IV's. And, all other twopoint weight functions lead to two-sided WAP tests that are not asymptotically efficient under strong IV's.

Lemma 14.2 Under the assumptions of Theorem 8 of AMS, i.e., Assumptions SIV-LA and 1-4 of AMS, (a) if $\left(\beta_{2 *}, \lambda_{2}\right)$ satisfies 14.4 , then $L R^{*}\left(\widehat{Q}_{1, n}, \widehat{Q}_{T, n} ; \beta_{*}, \lambda\right)=e^{-\frac{1}{2}\left(\tau^{*}\right)^{2}} \cosh \left(\tau^{*} L M_{n}^{1 / 2}\right)+o_{p}(1)$, where $\tau^{*}=\lambda^{1 / 2} c_{\beta_{*}}$, which is a strictly-increasing continuous function of $L M_{n}$, and (b) if $\left(\beta_{2 *}, \lambda_{2}\right)$ does not satisfy 14.4 , then $L R^{*}\left(\widehat{Q}_{1, n}, \widehat{Q}_{T, n} ; \beta_{*}, \lambda\right)=\eta_{2}\left(Q_{S T, n} / Q_{T, n}^{1 / 2}\right)+o_{p}(1)$ for a continuous function $\eta_{2}(\cdot)$ that is not even.

Comments. (i). Lemma 14.2 (a) is an extension of Theorem 8(b) of AMS; while Lemma 14.2 (b) is a correction to Theorem 8(c) of AMS.
(ii). The proofs of Lemma 14.1 and 14.2 are given in Section 19 below.

Having augmented (4.1) by (14.3), the two-point weight function of AMS does not have the property that $\beta_{2 *}$ is necessarily on the opposite side of $\beta_{0}$ from $\beta_{*}$. However, it does have the properties that (i) for any $\left(\beta_{*}, \lambda\right),\left(\beta_{2 *}, \lambda_{2}\right)$ is the only point that yields a two-point WAP test that is asymptotic efficient in a two-sided sense under strong IV's, (ii) the marginal distributions of $Q_{S}, Q_{T}$, and $Q_{S T}$ are the same under $\left(\beta_{*}, \lambda\right)$ and $\left(\beta_{2 *}, \lambda_{2}\right)$, and (iii) the joint distribution of $\left(Q_{S}, Q_{S T}, Q_{T}\right)$ under $\left(\beta_{*}, \lambda\right)$ is the same as that of $\left(Q_{S},-Q_{S T}, Q_{T}\right)$ under $\left(\beta_{2 *}, \lambda_{2}\right)$.

## 15 Proof of Lemma 6.1

The proof of Lemma 6.1 and other proofs below use the following lemma.
The distributions of [S:T] under $\left(\beta_{0}, \Omega\right)$ and $\left(\beta_{*}, \Omega\right)$ depend on $c_{\beta}\left(\beta_{0}, \Omega\right)$ and $d_{\beta}\left(\beta_{0}, \Omega\right)$ for $\beta=\beta_{0}$ and $\beta_{*}$. The limits of these quantities as $\beta_{0} \rightarrow \pm \infty$ are given in the following lemma. ${ }^{[2]}$

Lemma 15.1 For fixed $\beta_{*}$ and positive definite matrix $\Omega$, we have
(a) $\lim _{\beta_{0} \rightarrow \pm \infty} c_{\beta_{0}}\left(\beta_{0}, \Omega\right)=0$.
(b) $\lim _{\beta_{0} \rightarrow \pm \infty} c_{\beta_{*}}\left(\beta_{0}, \Omega\right)=\mp 1 / \sigma_{v}$.
(c) $\lim _{\beta_{0} \rightarrow \pm \infty} d_{\beta_{0}}\left(\beta_{0}, \Omega\right)=\infty$.
(d) $d_{\beta_{0}}\left(\beta_{0}, \Omega\right) /\left|\beta_{0}\right|=\frac{\omega_{2}}{\left(\omega_{1}^{2} \omega_{2}^{2}-\omega_{12}^{2}\right)^{1 / 2}}+o(1)=\frac{1}{\sigma_{u}\left(1-\rho_{u v}^{2}\right)^{1 / 2}}+o(1)$ as $\left|\beta_{0}\right| \rightarrow \infty$.
(e) $\lim _{\beta_{0} \rightarrow \pm \infty} d_{\beta_{*}}\left(\beta_{0}, \Omega\right)= \pm \frac{\omega_{2}^{2} \beta_{*}-\omega_{12}}{\omega_{2}\left(\omega_{1}^{2} \omega_{2}^{2}-\omega_{12}^{2}\right)^{1 / 2}}=\mp \frac{\rho_{u v}}{\sigma_{v}\left(1-\rho_{u v}^{2}\right)^{1 / 2}}$.

Comment. The limits in parts (d) and (e), expressed in terms of $\Sigma_{*}$, only depend on $\rho_{u v}, \sigma_{u}$, and $\sigma_{v}$ and their functional forms are of a relatively simple multiplicative form. The latter provides additional simplifications of certain quantities that appear below.

Proof of Lemma 15.1. Part (a) holds because $c_{\beta_{0}}\left(\beta_{0}, \Omega\right)=0$ for all $\beta_{0}$. Part (b) holds by the following calculations:

$$
\begin{align*}
\lim _{\beta_{0} \rightarrow \pm \infty} c_{\beta_{*}}\left(\beta_{0}, \Omega\right) & =\lim _{\beta_{0} \rightarrow \pm \infty}\left(\beta_{*}-\beta_{0}\right) \cdot\left(b_{0}^{\prime} \Omega b_{0}\right)^{-1 / 2} \\
& =\lim _{\beta_{0} \rightarrow \pm \infty}\left(\beta_{*}-\beta_{0}\right) \cdot\left(\omega_{1}^{2}-2 \omega_{12} \beta_{0}+\omega_{2}^{2} \beta_{0}^{2}\right)^{-1 / 2} \\
& =\mp 1 / \omega_{2} \\
& =\mp 1 / \sigma_{v} . \tag{15.1}
\end{align*}
$$

Now, we establish part (e). Let $b_{*}:=\left(1,-\beta_{*}\right)^{\prime}$. We have

$$
\begin{align*}
\lim _{\beta_{0} \rightarrow \pm \infty} d_{\beta_{*}}\left(\beta_{0}, \Omega\right) & =\lim _{\beta_{0} \rightarrow \pm \infty} b_{*}^{\prime} \Omega b_{0} \cdot\left(b_{0}^{\prime} \Omega b_{0}\right)^{-1 / 2} \operatorname{det}(\Omega)^{-1 / 2} \\
& =\lim _{\beta_{0} \rightarrow \pm \infty} \frac{\omega_{1}^{2}-\omega_{12} \beta_{*}-\omega_{12} \beta_{0}+\omega_{2}^{2} \beta_{*} \beta_{0}}{\left(\omega_{1}^{2}-2 \omega_{12} \beta_{0}+\omega_{2}^{2} \beta_{0}^{2}\right)^{1 / 2}\left(\omega_{1}^{2} \omega_{2}^{2}-\omega_{12}^{2}\right)^{1 / 2}} \\
& = \pm \frac{\omega_{2}^{2} \beta_{*}-\omega_{12}}{\omega_{2}\left(\omega_{1}^{2} \omega_{2}^{2}-\omega_{12}^{2}\right)^{1 / 2}} . \tag{15.2}
\end{align*}
$$

Next, we write the limit in 15.2 in terms of the elements of the structural error variance matrix

[^10]$\Sigma_{*}$. The term in the square root in the denominator of 15.2 satisfies
\[

$$
\begin{equation*}
\omega_{1}^{2} \omega_{2}^{2}-\omega_{12}^{2}=\left(\sigma_{u}^{2}+2 \sigma_{u v} \beta_{*}+\sigma_{v}^{2} \beta_{*}^{2}\right) \sigma_{v}^{2}-\left(\sigma_{u v}+\sigma_{v}^{2} \beta_{*}\right)^{2}=\sigma_{u}^{2} \sigma_{v}^{2}-\sigma_{u v}^{2}, \tag{15.3}
\end{equation*}
$$

\]

where the first equality uses $\omega_{2}^{2}=\sigma_{v}^{2}$ (since both denote the variance of $v_{2 i}$ ), $\omega_{1}^{2}=\sigma_{u}^{2}+2 \sigma_{u v} \beta_{*}+$ $\sigma_{v}^{2} \beta_{*}^{2}$ ), and $\omega_{12}=\sigma_{u v}+\sigma_{v}^{2} \beta_{*}$ (which both hold by 12.8) with $\beta=\beta_{*}$ and $\Sigma=\Sigma_{*}$ ), and the second equality holds by simple calculations. The limit in (15.2) in terms of the elements of $\Sigma_{*}$ is

$$
\begin{equation*}
\pm \frac{\omega_{2}^{2} \beta_{*}-\omega_{12}}{\omega_{2}\left(\omega_{1}^{2} \omega_{2}^{2}-\omega_{12}^{2}\right)^{1 / 2}}= \pm \frac{\sigma_{v}^{2} \beta_{*}-\left(\sigma_{u v}+\sigma_{v}^{2} \beta_{*}\right)}{\sigma_{v}\left(\sigma_{u}^{2} \sigma_{v}^{2}-\sigma_{u v}^{2}\right)^{1 / 2}}=\mp \frac{\rho_{u v}}{\sigma_{v}\left(1-\rho_{u v}^{2}\right)^{1 / 2}}, \tag{15.4}
\end{equation*}
$$

where the first equality uses 15.3, $\omega_{2}^{2}=\sigma_{v}^{2}$, and $\omega_{12}=\sigma_{u v}+\sigma_{v}^{2} \beta_{*}$, and the second inequality holds by dividing the numerator and denominator by $\sigma_{u} \sigma_{v}$. This establishes part (e).

For part (c), we have

$$
\begin{align*}
\lim _{\beta_{0} \rightarrow \pm \infty} d_{\beta_{0}}\left(\beta_{0}, \Omega\right) & =\lim _{\beta_{0} \rightarrow \pm \infty}\left(b_{0}^{\prime} \Omega b_{0}\right)^{1 / 2} \operatorname{det}(\Omega)^{-1 / 2} \\
& =\lim _{\beta_{0} \rightarrow \pm \infty} \frac{\left(\omega_{1}^{2}-2 \omega_{12} \beta_{0}+\omega_{2}^{2} \beta_{0}^{2}\right)^{1 / 2}}{\left(\omega_{1}^{2} \omega_{2}^{2}-\omega_{12}^{2}\right)^{1 / 2}} \\
& =\infty \tag{15.5}
\end{align*}
$$

Part (d) holds because, as $\left|\beta_{0}\right| \rightarrow \infty$, we have

$$
\begin{align*}
d_{\beta_{0}}\left(\beta_{0}, \Omega\right) /\left|\beta_{0}\right| & =\frac{\left(\omega_{1}^{2} / \beta_{0}^{2}-2 \omega_{12} / \beta_{0}+\omega_{2}^{2}\right)^{1 / 2}}{\left(\omega_{1}^{2} \omega_{2}^{2}-\omega_{12}^{2}\right)^{1 / 2}} \\
& =\frac{\omega_{2}}{\left(\omega_{1}^{2} \omega_{2}^{2}-\omega_{12}^{2}\right)^{1 / 2}}+o(1) \\
& =\frac{1}{\sigma_{u}\left(1-\rho_{u v}^{2}\right)^{1 / 2}}+o(1) \tag{15.6}
\end{align*}
$$

where the last equality uses (15.3) and $\omega_{2}=\sigma_{v}$.
Next, we prove Lemma 6.1, which states that for any fixed $\left(\beta_{*}, \lambda, \Omega\right), \lim _{\beta_{0} \rightarrow \pm \infty} f_{Q}\left(q ; \beta_{*}, \beta_{0}, \lambda, \Omega\right)$ $=f_{Q}\left(q ; \rho_{u v}, \lambda_{v}\right)$.

Proof of Lemma 6.1. By Lemma 15.1(b) and (e) and 6.1], we have $\lim _{\beta_{0} \rightarrow \pm \infty} c_{\beta_{*}}=\mp 1 / \sigma_{v}$ and
$\lim _{\beta_{0} \rightarrow \pm \infty} d_{\beta_{*}}=\mp r_{u v} / \sigma_{v}$. In consequence,

$$
\begin{align*}
\lim _{\beta_{0} \rightarrow \pm \infty} \lambda\left(c_{\beta_{*}}^{2}+d_{\beta_{*}}^{2}\right) & =\lambda\left(1 / \sigma_{v}^{2}\right)\left(1+r_{u v}^{2}\right)=\lambda_{v}\left(1+r_{u v}^{2}\right) \text { and } \\
\lim _{\beta_{0} \rightarrow \pm \infty} \lambda \xi_{\beta_{*}}(q) & =\lim _{\beta_{0} \rightarrow \pm \infty} \lambda\left(c_{\beta_{*}}^{2} q_{S}+2 c_{\beta_{*}} d_{\beta_{*}} q_{S T}+d_{\beta_{*}}^{2} q_{T}\right) \\
& =\lambda\left(1 / \sigma_{v}^{2}\right)\left(q_{S}+2 r_{u v} q_{S T}+r_{u v}^{2} q_{T}\right)=\lambda_{v} \xi\left(q ; \rho_{u v}\right), \tag{15.7}
\end{align*}
$$

using the definitions of $\lambda_{v}$ and $\xi\left(q ; \rho_{u v}\right)$ in (6.1) and (12.4), respectively, where the first equality in the third line uses $(\mp 1)\left(\mp r_{u v}\right)=r_{u v}$. Combining this with (12.2) and (12.4) proves the result of the lemma.

## 16 Proof of Theorem 5.1

The proof of Theorem 5.1 uses the following lemma ${ }^{[13}$ Let

$$
\begin{align*}
& S_{ \pm \infty}(Y):=\left(Z^{\prime} Z\right)^{-1 / 2} Z^{\prime} Y e_{2} \cdot \frac{\mp 1}{\sigma_{v}}, \\
& T_{ \pm \infty}(Y):=\left(Z^{\prime} Z\right)^{-1 / 2} Z^{\prime} Y \Omega^{-1} e_{1} \cdot\left( \pm\left(1-\rho_{u v}^{2}\right)^{1 / 2} \sigma_{u}\right), \text { and } \\
& Q_{ \pm \infty}(Y):=\left[\begin{array}{cc}
e_{2}^{\prime} Y^{\prime} P_{Z} Y e_{2} \cdot \frac{1}{\sigma_{v}^{2}} & e_{2}^{\prime} Y^{\prime} P_{Z} Y \Omega^{-1} e_{1} \cdot \frac{\mp\left(1-\rho_{u v}^{2}\right)^{1 / 2} \sigma_{u}}{\sigma_{v}} \\
e_{2}^{\prime} Y^{\prime} P_{Z} Y \Omega^{-1} e_{1} \cdot \frac{\mp\left(1-\rho_{u v}^{2}\right)^{1 / 2} \sigma_{u}}{\sigma_{v}} & e_{1}^{\prime} \Omega^{-1} Y^{\prime} P_{Z} Y \Omega^{-1} e_{1} \cdot\left(1-\rho_{u v}^{2}\right) \sigma_{u}^{2}
\end{array}\right], \tag{16.1}
\end{align*}
$$

where $\rho_{u v}:=\operatorname{Corr}\left(u_{i}, v_{2 i}\right), P_{Z}:=Z\left(Z^{\prime} Z\right)^{-1} Z^{\prime}, e_{1}:=(1,0)^{\prime}$, and $e_{2}:=(0,1)^{\prime}$. Let $Q_{T, \pm \infty}(Y)$ denote the $(2,2)$ element of $Q_{ \pm \infty}(Y)$. As defined in 6.1, $r_{u v}=\rho_{u v} /\left(1-\rho_{u v}^{2}\right)^{1 / 2}$.

Lemma 16.1 For fixed $\beta_{*}$ and positive definite matrix $\Omega$, we have
(a) $\lim _{\beta_{0} \rightarrow \pm \infty} S_{\beta_{0}}(Y)=S_{ \pm \infty}(Y)$,
(b) $S_{ \pm \infty}(Y) \sim N\left(\mp \frac{1}{\sigma_{v}} \mu_{\pi}, I_{k}\right)$,
(c) $\lim _{\beta_{0} \rightarrow \pm \infty} T_{\beta_{0}}(Y)=T_{ \pm \infty}(Y)=\left(Z^{\prime} Z\right)^{-1 / 2} Z^{\prime} Y \Omega^{-1} e_{1} \cdot\left( \pm\left(1-\rho_{\Omega}^{2}\right)^{1 / 2} \omega_{1}\right)$, where $\rho_{\Omega}:=\operatorname{Corr}\left(v_{1 i}, v_{2 i}\right)$,
(d) $T_{ \pm \infty}(Y) \sim N\left(\mp \frac{r_{u v}}{\sigma_{v}} \mu_{\pi}, I_{k}\right)$,
(e) $S_{ \pm \infty}(Y)$ and $T_{ \pm \infty}(Y)$ are independent,
(f) $\lim _{\beta_{0} \rightarrow \pm \infty} Q_{\beta_{0}}(Y)=Q_{ \pm \infty}(Y)$, and
(g) $Q_{ \pm \infty}(Y)$ has a noncentral Wishart distribution with means matrix $\mp \mu_{\pi}\left(\frac{1}{\sigma_{v}}, \frac{r_{u v}}{\sigma_{v}}\right) \in R^{k \times 2}$, identity variance matrix, and density given in (12.4).

Comment. The convergence results in Lemma 16.1 hold for all realizations of $Y$.

[^11]Proof of Theorem 5.1. First, we prove part (a). We have

$$
\begin{align*}
& 1\left(R \operatorname{Length}\left(C S_{\phi}(Y)\right)=\infty\right) \\
= & 1\left(\mathcal{T}\left(Q_{\beta_{0}}(Y)\right) \leq c v\left(Q_{T, \beta_{0}}(Y)\right) \forall \beta_{0} \geq K(Y) \text { for some } K(Y)<\infty\right) \\
= & \lim _{\beta_{0} \rightarrow \infty} 1\left(\mathcal{T}\left(Q_{\beta_{0}}(Y)\right) \leq c v\left(Q_{T, \beta_{0}}(Y)\right)\right), \tag{16.2}
\end{align*}
$$

where the second equality holds provided the limit as $\beta_{0} \rightarrow \infty$ on the rhs exists, the first equality holds by the definition of $C S_{\phi}(Y)$ in (5.1)-(5.3) and the definition of $R \operatorname{Length}\left(C S_{\phi}(Q)\right)=\infty$ in (5.4), and the second equality holds because its rhs equals one (when the rhs limit exists) iff $\mathcal{T}\left(Q_{\beta_{0}}(Y)\right) \leq c v\left(Q_{T, \beta_{0}}(Y)\right)$ for $\forall \beta_{0} \geq K(Y)$ for some $K(Y)<\infty$, which is the same as its lhs.

Now, we use the dominated convergence theorem to show

$$
\begin{align*}
& \lim _{\beta_{0} \rightarrow \infty} E_{\beta_{*}, \pi, \Omega} 1\left(\mathcal{T}\left(Q_{\beta_{0}}(Y)\right) \leq c v\left(Q_{T, \beta_{0}}(Y)\right)\right) \\
= & E_{\beta_{*}, \pi, \Omega} \lim _{\beta_{0} \rightarrow \infty} 1\left(\mathcal{T}\left(Q_{\beta_{0}}(Y)\right) \leq c v\left(Q_{T, \beta_{0}}(Y)\right)\right) . \tag{16.3}
\end{align*}
$$

The dominated convergence theorem applies because (i) the indicator functions in 16.3 ) are dominated by the constant function equal to one, which is integrable, and (ii) $\lim _{\beta_{0} \rightarrow \infty} 1\left(\mathcal{T}\left(Q_{\beta_{0}}(Y)\right) \leq\right.$ $\operatorname{cv}\left(Q_{T, \beta_{0}}(Y)\right)$ exists a.s. $\left[P_{\beta_{*}, \pi, \Omega}\right]$ and equals $1\left(\mathcal{T}\left(Q_{\infty}(Y)\right) \leq c v\left(Q_{T, \infty}(Y)\right)\right.$ a.s. $\left[P_{\beta_{*}, \pi, \Omega}\right]$. The latter holds because the assumption that $\mathcal{T}(q)$ and $c v\left(q_{T}\right)$ are continuous at positive definite (pd) $q$ and positive $q_{T}$, respectively, coupled with the result of Lemma 16.1(f) (that $Q_{\beta_{0}}(Y) \rightarrow Q_{\infty}(Y)$ as $\beta_{0} \rightarrow \infty$ for all sample realizations of $Y$, where $Q_{\infty}(Y)$ is defined in (16.1), imply that (a) $\lim _{\beta_{0} \rightarrow \infty} \mathcal{T}\left(Q_{\beta_{0}}(Y)\right)=\mathcal{T}\left(Q_{\infty}(Y)\right)$ for all realizations of $Y$ for which $Q_{\infty}(Y)$ is pd, (b) $\lim _{\beta_{0} \rightarrow \infty}$ $c v\left(Q_{T, \beta_{0}}(Y)\right)=c v\left(Q_{T, \infty}(Y)\right)$ for all realizations of $Y$ with $Q_{T, \infty}(Y)>0$, and hence (c) $\lim _{\beta_{0} \rightarrow \infty}$ $1\left(\mathcal{T}\left(Q_{\beta_{0}}(Y)\right) \leq \operatorname{cv}\left(Q_{T \beta_{0}}(Y)\right)=1\left(\mathcal{T}\left(Q_{\infty}(Y)\right) \leq c v\left(Q_{T, \infty}(Y)\right)\right.\right.$ for all realizations of $Y$ for which $\mathcal{T}\left(Q_{\infty}(Y)\right) \neq c v\left(Q_{T, \infty}(Y)\right)$. We have $P_{\beta_{*}, \pi, \Omega}\left(\mathcal{T}\left(Q_{\infty}(Y)\right)=c v\left(Q_{T, \infty}(Y)\right)\right)=0$ by assumption, and $P_{\beta_{*}, \pi, \Omega}\left(Q_{\infty}(Y)\right.$ is pd \& $\left.Q_{T, \infty}(Y)>0\right)=1$ (because $Q_{\infty}(Y)$ has a noncentral Wishart distribution by Lemma $16.1(\mathrm{~g})$ ). Thus, condition (ii) above holds and the DCT applies.

Next, we have

$$
\begin{align*}
& 1-\lim _{\beta_{0} \rightarrow \infty} P_{\beta_{*}, \beta_{0}, \lambda, \Omega}(\phi(Q)=1) \\
= & \lim _{\beta_{0} \rightarrow \infty} E_{\beta_{*}, \pi, \Omega} 1\left(\mathcal{T}\left(Q_{\beta_{0}}(Y)\right) \leq \operatorname{cv}\left(Q_{T, \beta_{0}}(Y)\right)\right) \\
= & E_{\beta_{*}, \pi, \Omega} \lim _{\beta_{0} \rightarrow \infty} 1\left(\mathcal{T}\left(Q_{\beta_{0}}(Y)\right) \leq c v\left(Q_{T, \beta_{0}}(Y)\right)\right) \\
= & P_{\beta_{*}, \pi, \Omega}\left(R \operatorname{Length}\left(C S_{\phi}(Y)\right)=\infty\right), \tag{16.4}
\end{align*}
$$

where the first equality holds because the distribution of $Q$ under $P_{\beta_{*}, \beta_{0}, \lambda, \Omega}(\cdot)$ equals the distribution of $Q_{\beta_{0}}(Y)$ under $P_{\beta_{*}, \pi, \Omega}(\cdot)$ and $\phi(Q)=0$ iff $\mathcal{T}\left(Q_{\beta_{0}}\right) \leq c v\left(Q_{T}\right)$ by 5.2 , the second equality holds by (16.3), and the last equality holds by (16.2). Equation (16.4) establishes part (a).

The proof of part (b) is the same as that of part (a), but with LLength, $\forall \beta_{0} \leq-K(Y)$, $\beta_{0} \rightarrow-\infty, Q_{-\infty}(Y)$, and $Q_{T,-\infty}(Y)$ in place of RLength, $\forall \beta_{0} \geq K(Y), \beta_{0} \rightarrow \infty, Q_{\infty}(Y)$, and $Q_{T, \infty}(Y)$, respectively.

The proof of part (c) uses the following: (i) $Q_{\infty}(Y)$ and $Q_{-\infty}(Y)$ only differ in the sign of their off-diagonal elements by 16.1), (ii) $\mathcal{T}\left(Q_{\infty}(Y)\right)$ does not depend on the sign of the off-diagonal element of $Q_{\infty}(Y)$ by assumption, and hence, (iii) $1\left(\mathcal{T}\left(Q_{\infty}(Y)\right) \leq c v\left(Q_{T, \infty}(Y)\right)=1\left(\mathcal{T}\left(Q_{-\infty}(Y)\right)\right.\right.$ $\leq c v\left(Q_{T,-\infty}(Y)\right)$ for all sample realizations of $Y$. We have

$$
\begin{align*}
& 1\left(R L^{2} n g t h\left(C S_{\phi}(Y)\right)=\infty \& L \operatorname{Length}\left(C S_{\phi}(Y)\right)=\infty\right) \\
= & 1\left(\mathcal{T}\left(Q_{\beta_{0}}(Y)\right) \leq c v\left(Q_{T \beta_{0}}(Y)\right) \forall \beta_{0} \geq K(Y) \& \forall \beta_{0} \leq-K(Y) \text { for some } K(Y)<\infty\right) \\
= & \lim _{\beta_{0} \rightarrow \infty} 1\left(\mathcal{T}\left(Q_{\beta_{0}}(Y)\right) \leq c v\left(Q_{T, \beta_{0}}(Y)\right) \& \mathcal{T}\left(Q_{-\beta_{0}}(Y)\right) \leq c v\left(Q_{T,-\beta_{0}}(Y)\right)\right) \\
= & 1\left(\mathcal{T}\left(Q_{\infty}(Y)\right) \leq c v\left(Q_{T, \infty}(Y)\right) \& \mathcal{T}\left(Q_{-\infty}(Y)\right) \leq c v\left(Q_{T,-\infty}(Y)\right)\right) \\
= & 1\left(\mathcal{T}\left(Q_{\infty}(Y)\right) \leq c v\left(Q_{T, \infty}(Y)\right)\right. \\
= & \lim _{\beta_{0} \rightarrow \infty} 1\left(\mathcal{T}\left(Q_{\beta_{0}}(Y)\right) \leq c v\left(Q_{T, \beta_{0}}(Y)\right)\right. \tag{16.5}
\end{align*}
$$

where the first two equalities hold for the same reasons as the equalities in 16.2 , the third equality holds a.s. $\left[P_{\beta_{*}, \pi, \Omega}\right]$ by result (ii) that follows $(16.3)$ and the same result with $-\beta_{0}$ and $-\infty$ in place of $\beta_{0}$ and $\infty$, respectively, the second last equality holds by condition (iii) immediately above (16.5), and the last equality holds by result (ii) that follows 16.3).

Now, we have

$$
\begin{align*}
& P_{\beta_{*}, \pi, \Omega}\left(R L e n g t h\left(C S_{\phi}(Y)\right)=\infty \& \operatorname{LLength}\left(C S_{\phi}(Y)\right)=\infty\right) \\
= & E_{\beta_{*}, \pi, \Omega} \lim _{\beta_{0} \rightarrow \infty} 1\left(\mathcal{T}\left(Q_{\beta_{0}}(Y)\right) \leq c v\left(Q_{T, \beta_{0}}(Y)\right)\right) \\
= & 1-\lim _{\beta_{0} \rightarrow \infty} P_{\beta_{*}, \beta_{0}, \lambda, \Omega}(\phi(Q)=1), \tag{16.6}
\end{align*}
$$

where the first equality holds by 16.5 and the second equality holds by the first four lines of (16.4). This establishes the equality in part (c) when $\beta_{0} \rightarrow \infty$. The equality in part (c) when $\beta_{0} \rightarrow-\infty$ holds because (16.5) and 16.6) hold with $\beta_{0} \rightarrow \infty$ replaced by $\beta_{0} \rightarrow-\infty$ since the indicator function on the rhs of the second equality in 16.5 depends on $\beta_{0}$ only through $\left|\beta_{0}\right|$.

Proof of Lemma 16.1. Part (a) holds because

$$
\begin{align*}
\lim _{\beta_{0} \rightarrow \pm \infty} S_{\beta_{0}}(Y) & =\lim _{\beta_{0} \rightarrow \pm \infty}\left(Z^{\prime} Z\right)^{-1 / 2} Z^{\prime} Y b_{0} \cdot\left(b_{0}^{\prime} \Omega b_{0}\right)^{-1 / 2} \\
& =\left(Z^{\prime} Z\right)^{-1 / 2} Z^{\prime} Y \lim _{\beta_{0} \rightarrow \pm \infty}\binom{1}{-\beta_{0}} /\left(\omega_{1}^{2}-2 \omega_{12} \beta_{0}+\omega_{2}^{2} \beta_{0}^{2}\right)^{1 / 2} \\
& =\left(Z^{\prime} Z\right)^{-1 / 2} Z^{\prime} Y e_{2}\left(\mp 1 / \sigma_{v}\right), \tag{16.7}
\end{align*}
$$

where $e_{2}:=(0,1)^{\prime}$, the first equality holds by (2.3), the second equality holds because $b_{0}:=$ $\left(1,-\beta_{0}\right)^{\prime}$, and the third equality holds using $\omega_{2}=\sigma_{v}$.

Next, we prove part (b). The statistic $S_{ \pm \infty}(Y)$ has a multivariate normal distribution because it is a linear combination of multivariate normal random variables. The mean of $S_{ \pm \infty}(Y)$ is

$$
\begin{equation*}
E S_{ \pm \infty}(Y)=\left(Z^{\prime} Z\right)^{-1 / 2} Z^{\prime} Z\left[\pi \beta_{*}: \pi\right] e_{2} \cdot \frac{\mp 1}{\sigma_{v}}=\left(Z^{\prime} Z\right)^{1 / 2} \pi \cdot \frac{\mp 1}{\sigma_{v}}=\mu_{\pi} \cdot \frac{\mp 1}{\sigma_{v}}, \tag{16.8}
\end{equation*}
$$

where the first equality holds using (2.2) with $a=\left(\beta_{*}, 1\right)^{\prime}$ and 16.1). The variance matrix of $S_{ \pm \infty}(Y)$ is

$$
\begin{align*}
& \operatorname{Var}\left(S_{ \pm \infty}(Y)\right)=\operatorname{Var}\left(\left(Z^{\prime} Z\right)^{-1 / 2} Z^{\prime} Y e_{2}\right) / \sigma_{v}^{2}=\operatorname{Var}\left(\sum_{i=1}^{n}\left(Z^{\prime} Z\right)^{-1 / 2} Z_{i} Y_{i}^{\prime} e_{2}\right) / \sigma_{v}^{2} \\
= & \sum_{i=1}^{n} \operatorname{Var}\left(\left(Z^{\prime} Z\right)^{-1 / 2} Z_{i} Y_{i}^{\prime} e_{2}\right) / \sigma_{v}^{2}=\sum_{i=1}^{n}\left(Z^{\prime} Z\right)^{-1 / 2} Z_{i} Z_{i}\left(Z^{\prime} Z\right)^{-1 / 2} e_{2}^{\prime} \Omega e_{2} / \sigma_{v}^{2}=I_{k}, \tag{16.9}
\end{align*}
$$

where the third equality holds by independence across $i$ and the last equality uses $\omega_{2}^{2}=\sigma_{v}^{2}$. This establishes part (b).

To prove part (c), we have

$$
\begin{align*}
\lim _{\beta_{0} \rightarrow \pm \infty} T_{\beta_{0}}(Y) & =\lim _{\beta_{0} \rightarrow \pm \infty}\left(Z^{\prime} Z\right)^{-1 / 2} Z^{\prime} Y \Omega^{-1} a_{0} \cdot\left(a_{0}^{\prime} \Omega^{-1} a_{0}\right)^{-1 / 2} \\
& =\left(Z^{\prime} Z\right)^{-1 / 2} Z^{\prime} Y \Omega^{-1} \lim _{\beta_{0} \rightarrow \pm \infty}\binom{\beta_{0}}{1} /\left(\omega^{11} \beta_{0}^{2}+2 \omega^{12} \beta_{0}+\omega^{22}\right)^{1 / 2} \\
& =\left(Z^{\prime} Z\right)^{-1 / 2} Z^{\prime} Y \Omega^{-1} e_{1} \cdot\left( \pm 1 / \omega^{11}\right)^{1 / 2} \\
& =\left(Z^{\prime} Z\right)^{-1 / 2} Z^{\prime} Y \Omega^{-1} e_{1} \cdot\left( \pm\left(\omega_{1}^{2} \omega_{2}^{2}-\omega_{12}^{2}\right)^{1 / 2} / \omega_{2}\right), \tag{16.10}
\end{align*}
$$

where $\omega^{11}, \omega^{12}$, and $\omega^{22}$ denote the $(1,1),(1,2)$, and $(2,2)$ elements of $\Omega^{-1}$, respectively, $e_{1}:=(1,0)^{\prime}$, the first equality holds by (2.3), the second equality holds because $a_{0}:=\left(\beta_{0}, 1\right)^{\prime}$, and the fourth
equality holds by the formula for $\omega^{11}$. In addition, we have

$$
\begin{equation*}
\left(\omega_{1}^{2} \omega_{2}^{2}-\omega_{12}^{2}\right)^{1 / 2} / \omega_{2}=\left(1-\rho_{\Omega}^{2}\right)^{1 / 2} \omega_{1}=\left(1-\rho_{u v}^{2}\right)^{1 / 2} \sigma_{u} \tag{16.11}
\end{equation*}
$$

where the first equality uses $\rho_{\Omega}:=\omega_{12} /\left(\omega_{1} \omega_{2}\right)$ and the second equality holds because $\omega_{1}^{2} \omega_{2}^{2}-\omega_{12}^{2}=$ $\sigma_{u}^{2} \sigma_{v}^{2}-\sigma_{u v}^{2}$ by 15.3 and $\omega_{2}=\sigma_{v}$. Equations 16.10 and 16.11, combined with 16.1, establish part (c).

Now, we prove part (d). Like $S_{ \pm \infty}(Y), T_{ \pm \infty}(Y)$ has a multivariate normal distribution. The mean of $T_{ \pm \infty}(Y)$ is

$$
\begin{align*}
E T_{ \pm \infty}(Y) & =\left(Z^{\prime} Z\right)^{-1 / 2} Z^{\prime} Z\left[\pi \beta_{*}: \pi\right] \Omega^{-1} e_{1} \cdot\left( \pm\left(1-\rho_{u v}^{2}\right)^{1 / 2} \sigma_{u}\right) \\
& =\left(Z^{\prime} Z\right)^{1 / 2} \pi\left(\beta_{*} \omega^{11}+\omega^{12}\right) \cdot\left( \pm\left(1-\rho_{u v}^{2}\right)^{1 / 2} \sigma_{u}\right), \tag{16.12}
\end{align*}
$$

where the equality holds using (2.2) with $a=\left(\beta_{*}, 1\right)^{\prime}$ and 16.1). In addition, we have

$$
\begin{equation*}
\beta_{*} \omega^{11}+\omega^{12}=\frac{\beta_{*} \omega_{2}^{2}-\omega_{12}}{\omega_{1}^{2} \omega_{2}^{2}-\omega_{12}^{2}}=\frac{-\sigma_{u v}}{\sigma_{u}^{2} \sigma_{v}^{2}-\sigma_{u v}^{2}}=\frac{-\rho_{u v}}{\left(1-\rho_{u v}^{2}\right) \sigma_{u} \sigma_{v}}, \tag{16.13}
\end{equation*}
$$

where the second equality uses $\omega_{1}^{2} \omega_{2}^{2}-\omega_{12}^{2}=\sigma_{u}^{2} \sigma_{v}^{2}-\sigma_{u v}^{2}$ by 15.3) and $\beta_{*} \omega_{2}^{2}-\omega_{12}=-\sigma_{u v}$ by (12.9) with $\beta=\beta_{*}$. Combining (16.12) and (16.13) gives

$$
\begin{equation*}
E T_{ \pm \infty}(Y)=\mu_{\pi} \cdot \frac{\mp \rho_{u v}}{\sigma_{v}\left(1-\rho_{u v}^{2}\right)^{1 / 2}}=\mu_{\pi} \cdot \frac{\mp r_{u v}}{\sigma_{v}} . \tag{16.14}
\end{equation*}
$$

The variance matrix of $T_{ \pm \infty}(Y)$ is

$$
\begin{aligned}
& \operatorname{Var}\left(T_{ \pm \infty}(Y)\right)=\operatorname{Var}\left(\left(Z^{\prime} Z\right)^{-1 / 2} Z^{\prime} Y \Omega^{-1} e_{1}\right) \cdot\left(1-\rho_{u v}^{2}\right) \sigma_{u}^{2} \\
= & \operatorname{Var}\left(\sum_{i=1}^{n}\left(Z^{\prime} Z\right)^{-1 / 2} Z_{i} Y_{i}^{\prime} \Omega^{-1} e_{1}\right) \cdot\left(1-\rho_{u v}^{2}\right) \sigma_{u}^{2}=\sum_{i=1}^{n} \operatorname{Var}\left(\left(Z^{\prime} Z\right)^{-1 / 2} Z_{i} Y_{i}^{\prime} \Omega^{-1} e_{1}\right) \cdot\left(1-\rho_{u v}^{2}\right) \sigma_{u}^{2} \\
= & \sum_{i=1}^{n}\left(Z^{\prime} Z\right)^{-1 / 2} Z_{i} Z_{i}\left(Z^{\prime} Z\right)^{-1 / 2} e_{1}^{\prime} \Omega^{-1} e_{1} \cdot\left(1-\rho_{u v}^{2}\right) \sigma_{u}^{2}=I_{k} \frac{\omega_{2}^{2}}{\omega_{1}^{2} \omega_{2}^{2}-\omega_{12}^{2}} \cdot\left(1-\rho_{u v}^{2}\right) \sigma_{u}^{2} \\
= & I_{k} \frac{\sigma_{v}^{2}}{\sigma_{u}^{2} \sigma_{v}^{2}-\sigma_{u v}^{2}} \cdot\left(1-\rho_{u v}^{2}\right) \sigma_{u}^{2}=I_{k},
\end{aligned}
$$

where the first equality holds by 16.1 , the third equality holds by independence across $i$, and the second last equality uses $\omega_{1}^{2} \omega_{2}^{2}-\omega_{12}^{2}=\sigma_{u}^{2} \sigma_{v}^{2}-\sigma_{u v}^{2}$ by 15.3) and $\omega_{2}^{2}=\sigma_{v}^{2}$.

Part (e) holds because

$$
\begin{align*}
\operatorname{Cov}\left(S_{ \pm \infty}(Y), T_{ \pm \infty}(Y)\right) & =-\sum_{i=1}^{n} \operatorname{Cov}\left(\left(Z^{\prime} Z\right)^{-1 / 2} Z_{i} Y_{i}^{\prime} e_{2},\left(Z^{\prime} Z\right)^{-1 / 2} Z_{i} Y_{i}^{\prime} \Omega^{-1} e_{1}\right) \cdot\left(1-\rho_{u v}^{2}\right)^{1 / 2} \sigma_{u} / \sigma_{v} \\
& =\sum_{i=1}^{n}\left(Z^{\prime} Z\right)^{-1 / 2} Z_{i} Z_{i}\left(Z^{\prime} Z\right)^{-1 / 2} e_{2}^{\prime} \Omega \Omega^{-1} e_{1} \cdot\left(1-\rho_{u v}^{2}\right)^{1 / 2} \sigma_{u} / \sigma_{v}=0^{k} \cdot(16.15) \tag{16.15}
\end{align*}
$$

Part (f) follows from parts (a) and (c) of the lemma and 5.1).
Part (g) holds by the definition of the noncentral Wishart distribution and parts (b), (d), and (e) of the lemma. The density of $Q_{ \pm \infty}(Y)$ equals the density in 12.4 because the noncentral Wishart density is invariant to a sign change in the means matrix.

## 17 Proofs of Theorems 6.2, Corollary 6.3, and Theorem 6.4

The following lemma is used in the proof of Theorem 6.2. As above, let $P_{\beta_{*}, \beta_{0}, \lambda, \Omega}(\cdot)$ and $P_{\rho_{u v}, \lambda_{v}}(\cdot)$ denote probabilities under the alternative hypothesis densities $f_{Q}\left(q ; \beta_{*}, \beta_{0}, \lambda, \Omega\right)$ and $f_{Q}\left(q ; \rho_{u v}, \lambda_{v}\right)$, which are defined in Section 12.1. See 12.2 and 12.4) for explicit expressions for these noncentral Wishart densities.

Lemma 17.1 (a) $\lim _{\beta_{0} \rightarrow \pm \infty} P_{\beta_{*}, \beta_{0}, \lambda, \Omega}\left(\operatorname{POIS2}\left(Q ; \beta_{*}, \beta_{0}, \lambda\right)>\kappa_{2, \beta_{0}}\left(Q_{T}\right)\right)=P_{\rho_{u v}, \lambda_{v}}(P O I S 2(Q ; \infty$, $\left.\left.\left|\rho_{u v}\right|, \lambda_{v}\right)>\kappa_{2, \infty}\left(Q_{T}\right)\right)$,
(b) $\lim _{\beta_{0} \rightarrow \pm \infty} P_{\beta_{2 *}, \beta_{0}, \lambda_{2}, \Omega}\left(\operatorname{POIS} 2\left(Q ; \beta_{*}, \beta_{0}, \lambda\right)>\kappa_{2, \beta_{0}}\left(Q_{T}\right)\right)=P_{-\rho_{u v}, \lambda_{v}}\left(\operatorname{POIS2}\left(Q ; \infty,\left|\rho_{u v}\right|, \lambda_{v}\right)\right.$ $\left.>\kappa_{2, \infty}\left(Q_{T}\right)\right)$,
(c) $P_{\rho_{u v}, \lambda_{v}}\left(\operatorname{POIS2}\left(Q ; \infty,\left|\rho_{u v}\right|, \lambda_{v}\right)>\kappa_{2, \infty}\left(Q_{T}\right)\right)=P_{-\rho_{u v}, \lambda_{v}}\left(\operatorname{POIS2}\left(Q ; \infty,\left|\rho_{u v}\right|, \lambda_{v}\right)>\kappa_{2, \infty}\left(Q_{T}\right)\right)$,
(d) $\lim _{\beta_{0} \rightarrow \pm \infty} \beta_{2 *}=-\beta_{*}+2 \frac{\omega_{12}}{\omega_{2}^{2}}=\beta_{*}+2 \frac{\sigma_{u} \rho_{u v}}{\sigma_{v}}$, and
(e) $\lim _{\beta_{0} \rightarrow \pm \infty} \lambda_{2}=\lambda$.

The reason that $Q$ has the density $f_{Q}\left(q ;-\rho_{u v}, \lambda_{v}\right)$ (defined in 12.4$)$ in the limit expression in Lemma 17.1 (b) can be seen clearly from the following lemma.

Lemma 17.2 For any fixed $\left(\beta_{*}, \lambda, \Omega\right), \lim _{\beta_{0} \rightarrow \pm \infty} f_{Q}\left(q ; \beta_{2 *}, \beta_{0}, \lambda_{2}, \Omega\right)=f_{Q}\left(q ;-\rho_{u v}, \lambda_{v}\right)$ for all $2 \times 2$ variance matrices $q$, where $\beta_{2 *}$ and $\lambda_{2}$ satisfy (6.3) and $\rho_{u v}$ and $\lambda_{v}$ are defined in (5.5) and (6.1), respectively.

Proof of Lemma 17.2. Given $\left(\beta^{*}, \lambda^{*}\right)$, suppose the second point $\left(\beta_{2}^{*}, \lambda_{2}^{*}\right)$ solves (14.1). In this case, by Lemma 15.1(b) and (e), we have

$$
\begin{align*}
\lim _{\beta_{0} \rightarrow \pm \infty} \lambda_{2}^{1 / 2} c_{\beta_{2 *}}\left(\beta_{0}, \Omega\right) & =\lim _{\beta_{0} \rightarrow \pm \infty}-\lambda^{1 / 2} c_{\beta_{*}}\left(\beta_{0}, \Omega\right)= \pm \lambda^{1 / 2} / \sigma_{v}= \pm \lambda_{v}^{1 / 2} \text { and }  \tag{17.1}\\
\lim _{\beta_{0} \rightarrow \pm \infty} \lambda_{2}^{1 / 2} d_{\beta_{2 *}}\left(\beta_{0}, \Omega\right) & =\lim _{\beta_{0} \rightarrow \pm \infty} \lambda^{1 / 2} d_{\beta_{*}}\left(\beta_{0}, \Omega\right)=\mp \lambda^{1 / 2} \frac{\rho_{u v}}{\sigma_{v}\left(1-\rho_{u v}^{2}\right)^{1 / 2}}=\mp \lambda_{v}^{1 / 2} r_{u v} .
\end{align*}
$$

Using (12.1), (12.4), and (17.1), we obtain

$$
\begin{align*}
\lim _{\beta_{0} \rightarrow \pm \infty} \lambda_{2}\left(c_{\beta_{2 *}}^{2}+d_{\beta_{2 *}}^{2}\right) & =\lambda_{v}\left(1+r_{u v}^{2}\right) \text { and } \\
\lim _{\beta_{0} \rightarrow \pm \infty} \lambda_{2} \xi_{\beta_{2 *}}(q) & :=\lim _{\beta_{0} \rightarrow \pm \infty} \lambda_{2}\left(c_{\beta_{2 *}}^{2} q_{S}+2 c_{\beta_{2 *}} d_{\beta_{2 *}} q_{S T}+d_{\beta_{2 *}}^{2} q_{T}\right) \\
& =\lambda_{v}\left(q_{S}-2 r_{u v} q_{S T}+r_{u v}^{2} q_{T}\right) \\
& =: \lambda_{v} \xi\left(q ;-\rho_{u v}\right), \tag{17.2}
\end{align*}
$$

On the other hand, given $\left(\beta^{*}, \lambda^{*}\right)$, suppose the second point $\left(\beta_{2}^{*}, \lambda_{2}^{*}\right)$ solves 14.3). In this case, the minus sign on the rhs side of the first equality on the first line of (17.1) disappears, the quantity on the rhs side of the last equality on the first line of 17.1 becomes $\mp \lambda_{v}^{1 / 2}$, a minus sign is added to the rhs side of the first equality on the second line of (17.1), and the quantity on the rhs side of the last equality on the second line of 17.1 becomes $\pm \lambda_{v}^{1 / 2} r_{u v}$. These changes leave $\lambda_{2} c_{\beta_{2 *}}^{2}, \lambda_{2} d_{\beta_{2 *}}^{2}$, and $\lambda_{2} c_{\beta_{2 *}} d_{\beta_{2 *}}$ unchanged from the case where $\left(\beta_{2}^{*}, \lambda_{2}^{*}\right)$ solves (14.1). Hence, 17.2) also holds when $\left(\beta_{2}^{*}, \lambda_{2}^{*}\right)$ solves 14.3 .

Combining $\sqrt{17.2}$ ) with 12.2 (with $\left(\beta_{2 *}, \lambda_{2}\right)$ in place of $\left(\beta_{*}, \lambda\right)$ ) and (12.4) proves the result of the lemma.

Proof of Theorem 6.2. By Theorem 3 of AMS, for all $\left(\beta_{*}, \beta_{0}, \lambda, \Omega\right)$,

$$
\begin{align*}
& P_{\beta_{*}, \beta_{0}, \lambda, \Omega}\left(\phi_{\beta_{0}}(Q)=1\right)+P_{\beta_{2 *}, \beta_{0}, \lambda_{2}, \Omega}\left(\phi_{\beta_{0}}(Q)=1\right)  \tag{17.3}\\
\leq & P_{\beta_{*}, \beta_{0}, \lambda, \Omega}\left(\operatorname{POIS} 2\left(Q ; \beta_{0}, \beta_{*}, \lambda\right)>\kappa_{2, \beta_{0}}\left(Q_{T}\right)\right)+P_{\beta_{2 *}, \beta_{0}, \lambda_{2}, \Omega}\left(\operatorname{POIS} 2\left(Q ; \beta_{0}, \beta_{*}, \lambda\right)>\kappa_{2, \beta_{0}}\left(Q_{T}\right)\right) .
\end{align*}
$$

That is, the test on the rhs maximizes the two-point average power for testing $\beta=\beta_{0}$ against $\left(\beta_{*}, \lambda\right)$ and $\left(\beta_{2 *}, \lambda_{2}\right)$ for fixed known $\Omega$.

Equation (17.3) and Lemma 17.1 (a)-(c) establish the result of Theorem 6.2 by taking the $\lim \sup _{\beta_{0} \rightarrow \pm \infty}$ of the lhs and the $\lim \inf _{\beta_{0} \rightarrow \pm \infty}$ of the rhs.

The proof of Comment (iv) to Theorem 6.2 is the same as that of Theorem 6.2, but in place of 17.3 it uses the inequality in Theorem 1 of CHJ i.e., $\int P_{\beta_{*}, \beta_{0}, \lambda, \mu_{\pi} /\left\|\mu_{\pi}\right\|, \Omega}\left(\phi_{\beta_{0}}(Q)=\right.$

1) $d U n i f\left(\mu_{\pi} /\left\|\mu_{\pi}\right\|\right) \leq \int P_{\beta_{*}, \beta_{0}, \lambda, \mu_{\pi} /\left\|\mu_{\pi}\right\|, \Omega}\left(\operatorname{POIS2}\left(Q ; \beta_{0}, \beta_{*}, \lambda\right)>\kappa_{2, \beta_{0}}\left(Q_{T}\right)\right) d U n i f\left(\mu_{\pi} /\left\|\mu_{\pi}\right\|\right)$, plus the fact that the rhs expression equals $P_{\beta_{*}, \beta_{0}, \lambda, \Omega}\left(\operatorname{POIS} 2\left(Q ; \beta_{0}, \beta_{*}, \lambda\right)>\kappa_{2, \beta_{0}}\left(Q_{T}\right)\right)$ because the distribution of $Q$ only depends on $\mu_{\pi}$ through $\lambda=\mu_{\pi}^{\prime} \mu_{\pi}$.

Proof of Lemma 17.1. To prove part (a), we write

$$
\begin{align*}
& P_{\beta_{*}, \beta_{0}, \lambda, \Omega}\left(\operatorname{POIS} 2\left(Q ; \beta_{0}, \beta_{*}, \lambda\right)>\kappa_{2, \beta_{0}}\left(Q_{T}\right)\right) \\
= & \iint 1\left(\operatorname{POIS} 2\left(q ; \beta_{0}, \beta_{*}, \lambda\right)>\kappa_{2, \beta_{0}}\left(q_{T}\right)\right) \phi_{k}\left(s-c_{\beta_{*}} \mu_{\pi}\right) \phi_{k}\left(t-d_{\beta_{*}} \mu_{\pi}\right) d s d t, \text { and } \\
= & \iiint_{\rho_{u v}, \lambda_{v}}\left(\operatorname{POIS} 2\left(Q ; \infty,\left|\rho_{u v}\right|, \lambda_{v}\right)>\kappa_{2, \infty}\left(Q_{T}\right)\right) \tag{17.4}
\end{align*}
$$

where $\phi_{k}(x)$ for $x \in R^{k}$ denotes the density of $k$ i.i.d. standard normal random variables, $\lambda=\mu_{\pi}^{\prime} \mu_{\pi}$, $s, t \in R^{k}, q=[s: t]^{\prime}[s: t], q_{T}=t^{\prime} t, c_{\beta_{*}}=c_{\beta_{*}}\left(\beta_{0}, \Omega\right), d_{\beta_{*}}=d_{\beta_{*}}\left(\beta_{0}, \Omega\right)$, the $\mp$ signs in the last line are both + or both - , and the integral in the last line is the same whether both $\mp$ signs are + or - (by a change of variables calculation).

We have

$$
\begin{equation*}
\lim _{\beta_{0} \rightarrow \pm \infty} \phi_{k}\left(s-c_{\beta_{*}}\left(\beta_{0}, \Omega\right) \mu_{\pi}\right) \phi_{k}\left(t-d_{\beta_{*}}\left(\beta_{0}, \Omega\right) \mu_{\pi}\right)=\phi_{k}\left(s-\left(\mp 1 / \sigma_{v}\right) \mu_{\pi}\right) \phi_{k}\left(t-\left(\mp r_{u v} / \sigma_{v}\right) \mu_{\pi}\right) \tag{17.5}
\end{equation*}
$$

for all $s, t \in R^{k}$, by Lemma 15.1 (b) and (e) and the smoothness of the standard normal density function. By (6.4) and (12.5) and Lemma 15.1 (b) and (e), we have

$$
\begin{equation*}
\lim _{\beta_{0} \rightarrow \pm \infty} \operatorname{POIS} 2\left(q ; \beta_{0}, \beta_{*}, \lambda\right)=\operatorname{POIS} 2\left(q ; \infty,\left|\rho_{u v}\right|, \lambda_{v}\right) \tag{17.6}
\end{equation*}
$$

for all for $2 \times 2$ variance matrices $q$, for given $\left(\beta_{*}, \lambda, \Omega\right)$. In addition, we show below that $\lim _{\beta_{0} \rightarrow \pm \infty}$ $\kappa_{2, \beta_{0}}\left(q_{T}\right)=\kappa_{2, \infty}\left(q_{T}\right)$ for all $q_{T} \geq 0$. Combining these results gives the following convergence result:

$$
\begin{align*}
& \lim _{\beta_{0} \rightarrow \pm \infty} 1\left(\operatorname{POIS} 2\left(q ; \beta_{0}, \beta_{*}, \lambda\right)>\kappa_{2, \beta_{0}}\left(q_{T}\right)\right) \cdot \phi_{k}\left(s-c_{\beta_{*}}\left(\beta_{0}, \Omega\right) \mu_{\pi}\right) \phi_{k}\left(t-d_{\beta_{*}}\left(\beta_{0}, \Omega\right) \mu_{\pi}\right) \\
= & 1\left(\operatorname{POIS} 2\left(q ; \infty,\left|\rho_{u v}\right|, \lambda_{v}\right)>\kappa_{2, \infty}\left(q_{T}\right)\right) \cdot \phi_{k}\left(s-\left(\mp 1 / \sigma_{v}\right) \mu_{\pi}\right) \phi_{k}\left(t-\left(\mp r_{u v} / \sigma_{v}\right) \mu_{\pi}\right) \tag{17.7}
\end{align*}
$$

for all $[s: t]$ for which $\operatorname{POIS2}\left(q ; \infty,\left|\rho_{u v}\right|, \lambda_{v}\right)>\kappa_{2, \infty}\left(q_{T}\right)$ or $\operatorname{POIS2}\left(q ; \infty,\left|\rho_{u v}\right|, \lambda_{v}\right)<\kappa_{2, \infty}\left(q_{T}\right)$, where $[s: t], q$ and $\left(q_{S}, q_{S T}, q_{T}\right)$ are functionally related by $q=[s: t]^{\prime}[s: t]$ and the definitions in (12.2).

Given Lebesgue measure on the set of points $\left(s^{\prime}, t^{\prime}\right)^{\prime} \in R^{2 k}$, the induced measure on $\left(q_{S}, q_{S T}, q_{T}\right)$ $=\left(s^{\prime} s, s^{\prime} t, t^{\prime} t\right) \in R^{3}$ is absolutely continuous with respect to (wrt) Lebesgue measure on $R^{3}$ with
positive density only for positive definite $q$. (This follows from change of variables calculations. These calculations are analogous to those used to show that if $[S: T$ ] has the multivariate normal density $\phi_{k}\left(s-\left(\mp 1 / \sigma_{v}\right) \mu_{\pi}\right) \phi_{k}\left(t-\left(\mp r_{u v} / \sigma_{v}\right) \mu_{\pi}\right)$, then $Q$ has the density $f_{Q}\left(q ; \rho_{u v}, \lambda_{v}\right)$, which, viewed as a function of $\left(q_{S}, q_{S T}, q_{T}\right)$, is a density wrt Lebesgue measure on $R^{3}$ that is positive only for positive definite $q$.) The Lebesgue measure of the set of $\left(q_{S}, q_{S T}, q_{T}\right)$ for which $\operatorname{POIS2}\left(q ; \infty,\left|\rho_{u v}\right|, \lambda_{v}\right)=$ $\kappa_{2, \infty}\left(q_{T}\right)$ is zero. (This holds because (i) the definition of $\operatorname{POIS} 2\left(q ; \infty,\left|\rho_{u v}\right|, \lambda_{v}\right)$ in (6.4) implies that the Lebesgue measure of the set of $\left(q_{S}, q_{S T}\right)$ for which $\operatorname{POIS2}\left(q ; \infty,\left|\rho_{u v}\right|, \lambda_{v}\right)=\kappa_{2, \infty}\left(q_{T}\right)$ is zero for all $q_{T} \geq 0$ and (ii) the Lebesgue measure of the set of $\left(q_{S}, q_{S T}, q_{T}\right)$ for which $\operatorname{POIS2}\left(q ; \infty,\left|\rho_{u v}\right|, \lambda_{v}\right)$ $=\kappa_{2, \infty}\left(q_{T}\right)$ is obtained by integrating the set in (i) over $q_{T} \in R$ subject to the constraint that $q$ is positive definite.) In turn, this implies that the Lebesgue measure of the set of $\left(s^{\prime}, t^{\prime}\right)^{\prime}$ for which $\operatorname{POIS2}\left(q ; \infty,\left|\rho_{u v}\right|, \lambda_{v}\right)=\kappa_{2, \infty}\left(q_{T}\right)$ is zero. Hence, 17.7) verifies the a.s. (wrt Lebesgue measure on $R^{2 k}$ ) convergence condition required for the application of the DCT to obtain part (a) using (17.4).

Next, to verify the dominating function requirement of the DCT, we need to show that

$$
\begin{equation*}
\sup _{\beta_{0} \in R}\left|\phi_{k}\left(s-c_{\beta_{*}}\left(\beta_{0}, \Omega\right) \mu_{\pi}\right) \phi_{k}\left(t-d_{\beta_{*}}\left(\beta_{0}, \Omega\right) \mu_{\pi}\right)\right| \tag{17.8}
\end{equation*}
$$

is integrable wrt Lebesgue measure on $R^{2 k}$ (since the indicator functions in 17.7) are bounded by one). For any $0<c<\infty$ and $m \in R$, we have

$$
\begin{align*}
& \int \sup _{|m| \leq c} \exp \left(-(x-m)^{2} / 2\right) d x=2 \int_{0}^{\infty} \sup _{|m| \leq c} \exp \left(-x^{2} / 2+m x-m^{2} / 2\right) d x \\
\leq & 2 \int_{0}^{\infty} \exp \left(-x^{2} / 2+c x\right) d x=2 \int_{0}^{\infty} \exp \left(-(x-c)^{2} / 2+c^{2} / 2\right) d x<\infty \tag{17.9}
\end{align*}
$$

where the first equality holds by symmetry. This result yields the integrability of the dominating function in 17.8 because $\phi_{k}(\cdot)$ is a product of univariate standard normal densities and $\sup _{\beta_{0} \in R}\left|c_{\beta_{*}}\left(\beta_{0}, \Omega\right)\right|<\infty$ and $\sup _{\beta_{0} \in R}\left|d_{\beta_{*}}\left(\beta_{0}, \Omega\right)\right|<\infty$ are finite by Lemma 15.1(b) and (e) and continuity of $c_{\beta_{*}}\left(\beta_{0}, \Omega\right)$ and $d_{\beta_{*}}\left(\beta_{0}, \Omega\right)$ in $\beta_{0}$.

Hence, the DCT applies and it yields part (a).
It remains to show $\lim _{\beta_{0} \rightarrow \pm \infty} \kappa_{2, \beta_{0}}\left(q_{T}\right)=\kappa_{2, \infty}\left(q_{T}\right)$ for all $q_{T} \geq 0$. As noted above, $\lim _{\beta_{0} \rightarrow \pm \infty}$ $\operatorname{POIS2}\left(q ; \beta_{0}, \beta_{*}, \lambda\right)=\operatorname{POIS}\left(q ; \infty,\left|\rho_{u v}\right|, \lambda_{v}\right)$ for all $2 \times 2$ variance matrices $q$. Hence, $1\left(\operatorname{POIS} 2\left(Q ; \beta_{0}, \beta_{*}, \lambda\right) \leq x\right) \rightarrow 1\left(\operatorname{POIS} 2\left(Q ; \infty,\left|\rho_{u v}\right|, \lambda_{v}\right) \leq x\right)$ as $\beta_{0} \rightarrow \pm \infty$ for all $x \in R$ for which POIS2 $\left(Q ; \infty,\left|\rho_{u v}\right|, \lambda_{v}\right) \neq x$. We have $P_{Q_{1} \mid Q_{T}}\left(\operatorname{POIS} 2\left(Q ; \infty,\left|\rho_{u v}\right|, \lambda_{v}\right)=x \mid q_{T}\right)=0$ for all $q_{T} \geq 0$ by the absolute continuity of $\operatorname{POIS} 2\left(Q ; \infty,\left|\rho_{u v}\right|, \lambda_{v}\right)$ under $P_{Q_{1} \mid Q_{T}}\left(\cdot \mid q_{T}\right)$ (by the functional form of POIS2 $\left(Q ; \infty,\left|\rho_{u v}\right|, \lambda_{v}\right)$ and the absolute continuity of $Q_{1}$ under $P_{Q_{1} \mid Q_{T}}\left(\cdot \mid q_{T}\right)$, whose density
is given in (12.3)). Thus, by the DCT, for all $x \in R$,

$$
\begin{align*}
& \lim _{\beta_{0} \rightarrow \pm \infty} P_{Q_{1} \mid Q_{T}}\left(\operatorname{POIS} 2\left(Q ; \beta_{0}, \beta_{*}, \lambda\right) \leq x \mid q_{T}\right)=P_{Q_{1} \mid Q_{T}}\left(\operatorname{POIS} 2\left(Q ; \infty,\left|\rho_{u v}\right|, \lambda_{v}\right) \leq x \mid q_{T}\right) \text { and } \\
& \operatorname{POIS2}\left(Q ; \beta_{0}, \beta_{*}, \lambda\right) \rightarrow{ }_{d} \operatorname{POIS} 2\left(Q ; \infty,\left|\rho_{u v}\right| \cdot \lambda_{v}\right) \text { as } \beta_{0} \rightarrow \pm \infty \text { under } P_{Q_{1} \mid Q_{T}}\left(\cdot \mid q_{T}\right) . \tag{17.10}
\end{align*}
$$

The second line of (17.10), coupled with the fact that $\operatorname{POIS} 2\left(Q ; \infty,\left|\rho_{u v}\right|, \lambda_{v}\right)$ has a strictly increasing distribution function at its $1-\alpha$ quantile under $P_{Q_{1} \mid Q_{T}}\left(\cdot \mid q_{T}\right)$ for all $q_{T} \geq 0$ (which is shown below), implies that the $1-\alpha$ quantile of $\operatorname{POIS} 2\left(Q ; \beta_{0}, \beta_{*}, \lambda\right)$ under $P_{Q_{1} \mid Q_{T}}\left(\cdot \mid q_{T}\right)$ (i.e., $\left.\kappa_{2, \beta_{0}}\left(q_{T}\right)\right)$ converges as $\beta_{0} \rightarrow \pm \infty$ to the $1-\alpha$ quantile of $\operatorname{POIS} 2\left(Q ; \beta_{0}, \beta_{*}, \lambda\right)$ under $P_{Q_{1} \mid Q_{T}}\left(\cdot \mid q_{T}\right)$ (i.e., $\left.\kappa_{2, \infty}\left(q_{T}\right)\right)$. This can be proved by contradiction. First, suppose $\delta:=\lim \sup _{j \rightarrow \infty} \kappa_{2, j}\left(q_{T}\right)-$ $\kappa_{2, \infty}\left(q_{T}\right)>0$ (where each $j \in R$ represents some value of $\beta_{0}$ here). Then, there exists a subsequence $\left\{m_{j}: j \geq 1\right\}$ of $\{j: j \geq 1\}$ such that $\delta=\lim _{j \rightarrow \infty} \kappa_{2, m_{j}}\left(q_{T}\right)-\kappa_{2, \infty}\left(q_{T}\right)$. We have

$$
\begin{align*}
\alpha & =\lim _{j \rightarrow \infty} P_{Q_{1} \mid Q_{T}}\left(\operatorname{POIS} 2\left(Q ; m_{j}, \beta_{*}, \lambda\right)>\kappa_{2, m_{j}}\left(q_{T}\right) \mid q_{T}\right) \\
& \leq \lim _{j \rightarrow \infty} P_{Q_{1} \mid Q_{T}}\left(\text { POIS } 2\left(Q ; m_{j}, \beta_{*}, \lambda\right)>\kappa_{2, \infty}\left(q_{T}\right)+\delta / 2 \mid q_{T}\right) \\
& =P_{Q_{1} \mid Q_{T}}\left(\text { POIS2 }\left(Q ; \infty,\left|\rho_{u v}\right|, \lambda_{v}\right)>\kappa_{2, \infty}\left(q_{T}\right)+\delta / 2 \mid q_{T}\right) \\
& <P_{Q_{1} \mid Q_{T}}\left(\text { POIS } 2\left(Q ; \infty,\left|\rho_{u v}\right|, \lambda_{v}\right)>\kappa_{2, \infty}\left(q_{T}\right) \mid q_{T}\right) \\
& =\alpha, \tag{17.11}
\end{align*}
$$

where the first equality holds by the definition of $\kappa_{2, \beta_{0}}\left(q_{T}\right)$, the first inequality holds by the expression above for $\delta$, the second equality holds by the first line of 17.10 with $x=\kappa_{2, \infty}\left(q_{T}\right)+\delta / 2$, the second inequality holds because $\delta>0$ and the distribution function of $\operatorname{POIS2}\left(Q ; \infty,\left|\rho_{u v}\right|, \lambda_{v}\right)$ is strictly increasing at its $1-\alpha$ quantile $\kappa_{2, \infty}\left(q_{T}\right)$ under $P_{Q_{1} \mid Q_{T}}\left(\cdot \mid q_{T}\right)$ for all $q_{T} \geq 0$, and the last equality holds by the definition of $\kappa_{2, \infty}\left(q_{T}\right)$. Equation (17.11) is a contradiction, so $\delta \leq 0$. An analogous argument shows that $\lim \inf _{\beta_{0} \rightarrow \infty} \kappa_{2, \beta_{0}}\left(q_{T}\right)-\kappa_{2, \infty}\left(q_{T}\right)<0$ does not hold. Hence, $\lim _{\beta_{0} \rightarrow \infty} \kappa_{2, \beta_{0}}\left(q_{T}\right)=\kappa_{2, \infty}\left(q_{T}\right)$. An analogous argument shows that $\lim \inf _{\beta_{0} \rightarrow-\infty} \kappa_{2, \beta_{0}}\left(q_{T}\right)=$ $\kappa_{2, \infty}\left(q_{T}\right)$.

It remains to show that the distribution function of $\operatorname{POIS} 2\left(Q ; \infty,\left|\rho_{u v}\right|, \lambda_{v}\right)$ is strictly increasing at its $1-\alpha$ quantile $\kappa_{2, \infty}\left(q_{T}\right)$ under $P_{Q_{1} \mid Q_{T}}\left(\cdot \mid q_{T}\right)$ for all $q_{T} \geq 0$. This holds because (i) $\operatorname{POIS2}\left(Q ; \infty,\left|\rho_{u v}\right|, \lambda_{v}\right)$ is a nonrandom strictly increasing function of $\left(\xi\left(Q ; \rho_{u v}\right), \xi\left(Q ;-\rho_{u v}\right)\right)$ conditional on $T=t$ (specifically, $\operatorname{POIS2}\left(Q ; \infty,\left|\rho_{u v}\right|, \lambda_{v}\right)=C_{q_{T}} \sum_{j=0}^{\infty}\left[\left(\lambda_{v} \xi\left(Q ; \rho_{u v}\right)\right)^{j}+\left(\lambda_{v} \xi\left(Q ;-\rho_{u v}\right)\right)^{j}\right]$ $/\left(4^{j} j!\Gamma(\nu+j+1)\right)$, where $C_{q_{T}}$ is a constant that may depend on $q_{T}, \nu:=(k-2) / 2$, and $\Gamma(\cdot)$ is the gamma function, by (6.4) and (4.8) of AMS, which provides an expression for the modified Bessel function of the first kind $\left.I_{\nu}(x)\right)$, (ii) $\xi\left(Q ; \rho_{u v}\right)=\left(S+r_{u v} T\right)^{\prime}\left(S+r_{u v} T\right)$ and
$\xi\left(Q ;-\rho_{u v}\right)=\left(S-r_{u v} T\right)^{\prime}\left(S-r_{u v} T\right)$ have the same noncentral $\chi_{k}^{2}$ distribution conditional on $T=t$ (because $[S: T]$ has a multivariate normal distribution with means matrix given by (6.2) and identity variance matrix), (iii) $\left(\xi\left(Q ; \rho_{u v}\right), \xi\left(Q ;-\rho_{u v}\right)\right)$ has a positive density on $R_{+}^{2}$ conditional on $T=t$ and also conditional on $Q_{T}=q_{T}$ (because the latter conditional density is the integral of the former conditional density over $t$ such that $t^{\prime} t=q_{T}$ ), and hence, (iv) $\operatorname{POIS} 2\left(Q ; \infty,\left|\rho_{u v}\right|, \lambda_{v}\right)$ has a positive density on $R_{+}$conditional on $q_{T}$ for all $q_{T} \geq 0$. This completes the proof of part (a).

The proof of part (b) is the same as that of part (a), but with (i) $-c_{\beta_{*}}$ and $\pm 1 / \sigma_{v}$ in place of $c_{\beta_{*}}$ and $\mp 1 / \sigma_{v}$, respectively, in (17.4), 17.5), and 17.7), and (ii) $\pi_{2}$ in place of $\pi$, where

$$
\begin{align*}
& \pi_{2}:=M e_{1, k}, e_{1, k}:=(1,0, \ldots,)^{\prime} \in R^{k}, M:=\frac{\lambda^{1 / 2} g\left(\beta_{0}, \beta_{*}, \Omega\right)}{\left(e_{1, k}^{\prime} Z^{\prime} Z e_{1, k}\right)^{1 / 2}}, \\
& g\left(\beta_{0}, \beta_{*}, \Omega\right):=\frac{d_{\beta_{0}}+2 r_{\beta_{0}}\left(\beta_{*}-\beta_{0}\right)}{d_{\beta_{0}}}, \text { and } \lambda_{2}:=\mu_{\pi_{2}}^{\prime} \mu_{\pi_{2}} . \tag{17.12}
\end{align*}
$$

As defined, $\lambda_{2}$ satisfies 6.3) because

$$
\begin{equation*}
\lambda_{2}:=\mu_{\pi_{2}}^{\prime} \mu_{\pi_{2}}=\pi_{2}^{\prime} Z^{\prime} Z \pi_{2}=M^{2} e_{1, k}^{\prime} Z^{\prime} Z e_{1, k}=\lambda g^{2}\left(\beta_{0}, \beta_{*}, \Omega\right) . \tag{17.13}
\end{equation*}
$$

In addition, $\lambda_{2} \rightarrow \lambda$ as $\beta_{0} \rightarrow \pm \infty$ by 17.17) below. With the above changes, the proof of part (a) establishes part (b).

Part (c) holds because the test statistic POIS2 $\left(Q ; \infty,\left|\rho_{u v}\right|, \lambda_{v}\right)$ and critical value $\kappa_{2, \infty}\left(Q_{T}\right)$ only depend on $\rho_{u v}$ and $q_{S T}$ through $\left|\rho_{u v}\right|$ and $\left|q_{S T}\right|$, respectively, and the density $f_{Q}\left(q ; \rho_{u v}, \lambda_{v}\right)$ of $Q$ only depends on the sign of $\rho_{u v}$ through $r_{u v} q_{S T}$. In consequence, a change of variables from $\left(q_{S}, q_{S T}, q_{T}\right)$ to ( $q_{S},-q_{S T}, q_{T}$ ) establishes the result of part (c).

To prove part (d), we have

$$
\begin{align*}
& d_{\beta_{0}}=\left(a_{0}^{\prime} \Omega^{-1} a_{0}\right)^{1 / 2}=\frac{\omega_{2}^{2} \beta_{0}^{2}-2 \omega_{12} \beta_{0}+\omega_{1}^{2}}{\omega_{1}^{2} \omega_{2}^{2}-\omega_{12}^{2}}\left(a_{0}^{\prime} \Omega^{-1} a_{0}\right)^{-1 / 2} \text { and } \\
& r_{\beta_{0}}=e_{1}^{\prime} \Omega^{-1} a_{0}\left(a_{0}^{\prime} \Omega^{-1} a_{0}\right)^{-1 / 2}=\frac{\omega_{2}^{2} \beta_{0}-\omega_{12}}{\omega_{1}^{2} \omega_{2}^{2}-\omega_{12}^{2}}\left(a_{0}^{\prime} \Omega^{-1} a_{0}\right)^{-1 / 2}, \tag{17.14}
\end{align*}
$$

where the first equalities on lines one and two hold by (2.7) of AMS and (6.3), respectively. Next, we have

$$
\begin{align*}
\beta_{2 *} & =\beta_{0}-\frac{d_{\beta_{0}}\left(\beta_{*}-\beta_{0}\right)}{d_{\beta_{0}}+2 r_{\beta_{0}}\left(\beta_{*}-\beta_{0}\right)} \\
& =\frac{d_{\beta_{0}}\left(2 \beta_{0}-\beta_{*}\right)+2 r_{\beta_{0}}\left(\beta_{*}-\beta_{0}\right) \beta_{0}}{d_{\beta_{0}}+2 r_{\beta_{0}}\left(\beta_{*}-\beta_{0}\right)} \\
& =\frac{\left(\omega_{2}^{2} \beta_{0}^{2}-2 \omega_{12} \beta_{0}+\omega_{1}^{2}\right)\left(2 \beta_{0}-\beta_{*}\right)+2\left(\omega_{2}^{2} \beta_{0}-\omega_{12}\right)\left(\beta_{*} \beta_{0}-\beta_{0}^{2}\right)}{\left(\omega_{2}^{2} \beta_{0}^{2}-2 \omega_{12} \beta_{0}+\omega_{1}^{2}\right)+2\left(\omega_{2}^{2} \beta_{0}-\omega_{12}\right)\left(\beta_{*}-\beta_{0}\right)} \\
& =\frac{\beta_{0}^{2}\left(-\omega_{2}^{2} \beta_{*}-4 \omega_{12}+2 \omega_{2}^{2} \beta_{*}+2 \omega_{12}\right)+O\left(\beta_{0}\right)}{\beta_{0}^{2}\left(\omega_{2}^{2}-2 \omega_{2}^{2}\right)+O\left(\beta_{0}\right)} \\
& =\frac{\left(\omega_{2}^{2} \beta_{*}-2 \omega_{12}\right)+o(1)}{-\omega_{2}^{2}+o(1)} \\
& =-\beta_{*}+\frac{2 \omega_{12}}{\omega_{2}^{2}}+o(1), \tag{17.15}
\end{align*}
$$

where the third equality uses 17.14 and the two terms involving $\beta_{0}^{3}$ in the numerator of the rhs of the third equality cancel. Next, we have

$$
\begin{equation*}
-\beta_{*}+\frac{2 \omega_{12}}{\omega_{2}^{2}}=\frac{2\left(\omega_{12}-\omega_{2}^{2} \beta_{*}\right)+\omega_{2}^{2} \beta_{*}}{\omega_{2}^{2}}=\frac{2 \sigma_{u v}+\sigma_{v}^{2} \beta_{*}}{\sigma_{v}^{2}}=\beta_{*}+2 \frac{\sigma_{u v}}{\sigma_{v}^{2}}=\beta_{*}+2 \frac{\sigma_{u} \rho_{u v}}{\sigma_{v}} \tag{17.16}
\end{equation*}
$$

where the second equality uses 12.9 with $\beta=\beta_{*}$ and $\omega_{2}^{2}=\sigma_{v}^{2}$.
Next, we prove part (e). We have

$$
\begin{align*}
\left(\frac{\lambda_{2}}{\lambda}\right)^{1 / 2} & =\left|\frac{d_{\beta_{0}}+2 r_{\beta_{0}}\left(\beta_{*}-\beta_{0}\right)}{d_{\beta_{0}}}\right| \\
& =\left|\frac{\omega_{2}^{2} \beta_{0}^{2}-2 \omega_{12} \beta_{0}+\omega_{1}^{2}+2\left(\omega_{2}^{2} \beta_{0}-\omega_{12}\right)\left(\beta_{*}-\beta_{0}\right)}{\omega_{2}^{2} \beta_{0}^{2}-2 \omega_{12} \beta_{0}+\omega_{1}^{2}}\right| \\
& =\left|\frac{\beta_{0}^{2}\left(\omega_{2}^{2}-2 \omega_{2}^{2}\right)+\beta_{0}\left(-2 \omega_{12}+2 \omega_{2}^{2} \beta_{*}+2 \omega_{12}\right)+\omega_{1}^{2}-2 \omega_{12} \beta_{*}}{\omega_{2}^{2} \beta_{0}^{2}-2 \omega_{12} \beta_{0}+\omega_{1}^{2}}\right| \\
& =1+o(1) \tag{17.17}
\end{align*}
$$

where the first equality holds by (6.3) and the second equality uses 17.14 .

Proof of Corollary 6.3. We have

$$
\begin{align*}
& \left(P_{\beta_{*}, \lambda, \Omega}\left(R \operatorname{Length}\left(C S_{\phi}(Y)\right)=\infty\right)+P_{\beta_{2 *}, \lambda_{2}, \Omega}\left(R L e n g t h\left(C S_{\phi}(Y)\right)=\infty\right)\right) / 2 \\
= & 1-\lim _{\beta_{0} \rightarrow \infty}\left[P_{\beta_{*}, \beta_{0}, \lambda, \Omega}(\phi(Q)=1)+\lim _{\beta_{0} \rightarrow \infty} P_{\beta_{2 *}, \beta_{0}, \lambda_{2}, \Omega}(\phi(Q)=1)\right] / 2 \\
\geq & P_{\rho_{u v}, \lambda_{v}}\left(P O I S 2\left(Q ; \infty,\left|\rho_{u v}\right|, \lambda_{v}\right)>\kappa_{2, \infty}\left(Q_{T}\right)\right), \tag{17.18}
\end{align*}
$$

where the equality holds by Theorem 5.1 (a) with $\left(\beta_{*}, \lambda\right)$ and $\left(\beta_{2 *}, \lambda_{2 *}\right), P_{\beta_{*}, \lambda, \Omega}(\cdot)$ is equivalent to $P_{\beta_{*}, \pi, \Omega}(\cdot)$, which appears in Theorem 5.1(a) (because events determined by $\operatorname{CS}_{\phi}(Y)$ only depend on $\pi$ through $\lambda$, since $C S_{\phi}(Y)$ is based on rotation-invariant tests), and the inequality holds by Theorem 6.2 (a). This establishes the first result of part (a).

The second result of part (a) holds by the same calculations as in (17.18), but with LLength and $\beta_{0} \rightarrow-\infty$ in place of RLength and $\beta_{0} \rightarrow \infty$, respectively, using Theorem 5.1(b) in place of Theorem 5.1(a).

Part (b) holds by combining Theorem 5.1 (c) and Theorem 6.2 because, as noted in Comment (iii) to Theorem 6.2, the lim sup on the left-hand side in Theorem 6.2 is the average of two equal quantities.

Next, we prove Comment (ii) to Corollary 6.3. The proof is the same as that of Corollary 6.3, but using

$$
\begin{equation*}
\int P_{\beta_{*}, \lambda, \mu_{\pi} /\left\|\mu_{\pi}\right\|, \Omega}\left(R \operatorname{Length}\left(C S_{\phi}(Y)\right)=\infty\right) d U n i f\left(\mu_{\pi} /\left\|\mu_{\pi}\right\|\right)=1-\lim _{\beta_{0} \rightarrow \infty} P_{\beta_{*}, \beta_{0}, \lambda, \Omega}(\phi(Q)=1) \tag{17.19}
\end{equation*}
$$

and likewise with $\left(\beta_{2 *}, \lambda_{2}\right)$ in place of $\left(\beta_{*}, \lambda\right)$ in place of the first equality in (17.18). The proof of 17.19 is the same as the proof of Theorem 5.1(a) but with $Q_{\beta_{0}}(Y)$ and $Q_{T, \beta_{0}}(Y)$ replaced by $\left[S_{\beta_{0}}(Y), T_{\beta_{0}}(Y)\right]$, and $T_{\beta_{0}}(Y)$, respectively, throughout the proof, with $E_{\beta_{*}, \pi, \Omega}(\cdot)$ replaced by $\int E_{\beta_{*}, \lambda, \mu_{\pi} /\left\|\mu_{\pi}\right\|, \Omega}(\cdot) d U n i \operatorname{form}\left(\mu_{\pi} /\left\|\mu_{\pi}\right\|\right)$ in 16.3), and using Lemma 16.1(a) and (c) in place of Lemma 16.1 (f) when verifying the limit property (ii) needed for the dominated convergence theorem following (16.3).

Proof of Theorem 6.4. The proof is quite similar to, but much simpler than, the proof of part (a) of Lemma 17.1 with $\operatorname{POIS} 2\left(q ; \beta_{0}, \beta_{*}, \lambda\right)>\kappa_{2, \beta_{0}}\left(q_{T}\right)$ in 17.4 replaced by $q_{S}>\chi_{k, 1-\alpha}^{2} / k$ for the AR test, $q_{S T}^{2} / q_{T}>\chi_{1,1-\alpha}^{2}$ for the LM test, and $q_{S}-q_{T}+\left(\left(q_{S}-q_{T}\right)^{2}+4 q_{S T}^{2}\right)^{1 / 2}>2 \kappa_{L R, \alpha}\left(q_{T}\right)$ for the CLR test. The proof is much simpler because for the latter three tests neither the test statistics nor the critical values depend on $\beta_{0}$. The parameter $\beta_{0}$, for which the limit as $\beta_{0} \rightarrow \pm \infty$ is being considered, only enters through the multivariate normal densities in 17.4. The limits of these densities and an integrable dominating function for them have already been provided in the proof of Lemma 17.1 (a). The indicator function that appears in 17.7 is bounded by one regardless of which test appears in the indicator function. In addition, $P_{\beta_{*}, \rho_{u v}, \lambda_{v}}\left(A R=\chi_{k, 1-\alpha}^{2}\right)=0$ and $P_{\beta_{*}, \rho_{u v}, \lambda_{v}}\left(L M=\chi_{1,1-\alpha}^{2}\right)=0$ because the AR statistic has a noncentral $\chi_{k}^{2}$ distribution with noncentrality parameter $\lambda_{v}$ under $P_{\beta_{*}, \rho_{u v}, \lambda_{v}}$ (since $S \sim N\left(\mu_{\pi} / \sigma_{v}, I_{k}\right)$ by Lemma 6.1 and 6.2) and the conditional distribution of the $L M$ statistic given $T$ under $P_{\beta_{*}, \rho_{u v}, \lambda_{v}}$ is a noncentral $\chi^{2}$
distribution.
Next, we show $P_{\beta_{*}, \rho_{u v}, \lambda_{v}}\left(L R=\kappa_{L R, \alpha}\left(Q_{T}\right)\right)=0$. Let $J=A R-L M$. Then, $2 L R=J+L M-$ $Q_{T}+\left(\left(J+L M-Q_{T}\right)^{2}+4 L M \cdot Q_{T}\right)^{1 / 2}$. We can write $Q=[S: T]^{\prime}[S: T]$, where $[S: T]$ has a multivariate normal distribution with means matrix given by (6.2) and identity variance matrix. As shown below, conditional on $T=t, L M$ and $J$ have independent noncentral $\chi^{2}$ distributions with 1 and $k-1$ degrees of freedom, respectively. This implies that (i) the distribution of $L R$ conditional on $T=t$ is absolutely continuous, (ii) $P_{\beta_{*}, \rho_{u v}, \lambda_{v}}\left(L R=\kappa_{L R, \alpha}\left(Q_{T}\right) \mid T=t\right)=0$ for all $t \in R^{k}$, and (iii) $P_{\beta_{*}, \rho_{u v}, \lambda_{v}}\left(L R=\kappa_{L R, \alpha}\left(Q_{T}\right)\right)=0$. It remains to show that conditional on $Q_{T}=q_{T}, L M$ and $J$ have independent noncentral $\chi^{2}$ distributions. We can write $L M=S^{\prime} P_{T} S$ and $J=S^{\prime}\left(I_{k}-P_{T}\right) S$, where $P_{T}:=T\left(T^{\prime} T\right)^{-1} T^{\prime}$ and $S$ has a multivariate normal with identity variance matrix. This implies that $P_{T} S$ and $\left(I_{k}-P_{T}\right) S$ are independent conditional on $T=t$ and $L M$ and $J$ have independent noncentral $\chi^{2}$ distributions conditional on $T=t$ for all $t \in R^{k}$. This completes the proof.

## 18 Proof of Theorem 8.1

The proof of Theorem 8.1(a) uses the following lemma.
Lemma 18.1 Suppose $b_{1 x}=1+\delta_{x} / x$ and $b_{2 x}=1-\delta_{x} / x$, where $\delta_{x} \rightarrow \delta_{\infty} \neq 0$ as $x \rightarrow \infty$, $K_{j 1 x}=\left(b_{j x} x\right)^{\eta}$ for some $\eta \in R$ for $j=1,2$, and $K_{j 2 x} \rightarrow K_{\infty} \in(0, \infty)$ as $x \rightarrow \infty$ for $j=1,2$. Then, (a) as $x \rightarrow \infty$,

$$
\begin{aligned}
& \log \left(K_{11 x} K_{12 x} e^{b_{1 x} x}+K_{21 x} K_{22 x} e^{b_{2 x} x}\right)-x-\eta \log x-\log K_{\infty} \\
\rightarrow & \delta_{\infty}+\log \left(1+e^{-2 \delta_{\infty}}\right) \text { and }
\end{aligned}
$$

(b) the function $s(y):=y+\log \left(1+e^{-2 y}\right)$ for $y \in R$ is infinitely differentiable, symmetric about zero, strictly increasing for $y>0$, and hence, strictly increasing in $|y|$ for $|y|>0$.

Proof of Lemma 18.1. Part (a) holds by the following:

$$
\begin{align*}
& \log \left(K_{11 x} K_{12 x} e^{b_{1 x} x}+K_{21 x} K_{22 x} e^{b_{2 x} x}\right)-x-\eta \log x-\log K_{\infty} \\
= & \log \left(K_{11 x} K_{12 x} e^{b_{1 x} x}\left(1+\frac{K_{21 x} K_{22 x}}{K_{11 x} K_{12 x}} e^{\left(b_{2 x}-b_{1 x}\right) x}\right)\right)-x-\eta \log x-\log K_{\infty} \\
= & b_{1 x} x+\log K_{11 x}+\log \left(K_{12 x} / K_{\infty}\right)+\log \left(1+\frac{K_{21 x} K_{22 x}}{K_{11 x} K_{12 x}} e^{\left(b_{2 x}-b_{1 x}\right) x}\right)-x-\eta \log x \\
= & \delta_{x}+\eta \log \left(b_{1 x}\right)+\log \left(K_{12 x} / K_{\infty}\right)+\log \left(1+\frac{K_{21 x} K_{22 x}}{K_{11 x} K_{12 x}} e^{-2 \delta_{x}}\right) \\
\rightarrow & \delta_{\infty}+\log \left(1+e^{-2 \delta_{\infty}}\right), \tag{18.1}
\end{align*}
$$

where the third equality uses $b_{1 x} x-x=\delta_{x}$, $\log K_{11 x}=\eta \log \left(b_{1 x} x\right)=\eta \log \left(b_{1 x}\right)+\eta \log (x)$, and $b_{2 x}-b_{1 x}=-2 \delta_{x} / x$, and the convergence uses $\log \left(b_{1 x}\right)=\log (1+o(1)) \rightarrow 0, K_{12 x} / K_{\infty} \rightarrow 1$, $K_{21 x} / K_{11 x}=\left(b_{2 x} / b_{1 x}\right)^{\eta}=1+o(1)$, and $K_{22 x} / K_{12 x} \rightarrow 1$.

The function $s(y)$ is infinitely differentiable because $\log (x)$ and $e^{-2 y}$ are. The function $s(y)$ is symmetric about zero because

$$
\begin{align*}
& y+\log \left(1+e^{-2 y}\right)=-y+\log \left(1+e^{2 y}\right) \\
\Leftrightarrow & 2 y=\log \left(1+e^{2 y}\right)-\log \left(1+e^{-2 y}\right)=\log \left(\frac{1+e^{2 y}}{1+e^{-2 y}}\right)=\log \left(e^{2 y}\right)=2 y . \tag{18.2}
\end{align*}
$$

The function $s(y)$ is strictly increasing for $y>0$ because

$$
\begin{equation*}
\frac{d}{d y} s(y)=1-\frac{2 e^{-2 y}}{1+e^{-2 y}}=\frac{1-e^{-2 y}}{1+e^{-2 y}}=\frac{e^{2 y}-1}{e^{2 y}+1} \tag{18.3}
\end{equation*}
$$

which is positive for $y>0$. We have $s(y)=s(|y|)$ because $s(y)$ is symmetric about zero, and $(d / d|y|) s(|y|)>0$ for $|y|>0$ by (18.3). Hence, $s(y)$ is strictly increasing in $|y|$ for $|y|>0$.

Proof of Theorem 8.1. Without loss in generality, we prove the results for the case where $\operatorname{sgn}\left(d_{\beta_{*}}\right)$ is the same for all terms in the sequence as $\lambda d_{\beta_{*}}^{2} \rightarrow \infty$. Given 2.3 , without loss of generality, we can suppose that

$$
\begin{equation*}
S=c_{\beta_{*}} \mu_{\pi}+Z_{S} \text { and } T=d_{\beta_{*}} \mu_{\pi}+Z_{T} \tag{18.4}
\end{equation*}
$$

where $Z_{S}$ and $Z_{T}$ are independent $N\left(0^{k}, I_{k}\right)$ random vectors.
We prove part (c) first. The distribution of $Q$ depends on $\mu_{\pi}$ only through $\lambda$. In consequence, without loss of generality, we can assume that $\Upsilon:=\mu_{\pi} / \lambda^{1 / 2} \in R^{k}$ does not vary as $\lambda d_{\beta_{*}}^{2}$ and $\lambda^{1 / 2} c_{\beta_{*}}$ vary. The following establishes the a.s. convergence of the one-sided $L M$ test statistic: as
$\lambda d_{\beta_{*}}^{2} \rightarrow \infty$ and $\lambda^{1 / 2} c_{\beta_{*}} \rightarrow c_{\infty}$,

$$
\begin{align*}
\frac{Q_{S T}}{Q_{T}^{1 / 2}}= & \frac{\left(c_{\beta_{*}} \mu_{\pi}+Z_{S}\right)^{\prime}\left(d_{\beta_{*}} \mu_{\pi}+Z_{T}\right)}{\left(\left(d_{\beta_{*}} \mu_{\pi}+Z_{T}\right)^{\prime}\left(d_{\beta_{*}} \mu_{\pi}+Z_{T}\right)\right)^{1 / 2}} \\
= & \frac{\left(c_{\beta_{*}} \mu_{\pi}+Z_{S}\right)^{\prime}\left(d_{\beta_{*}} \mu_{\pi}+Z_{T}\right)}{\left(d_{\beta_{*}}^{2} \lambda\right)^{1 / 2}\left(1+o_{a . s .}(1)\right)} \\
= & \frac{\left(c_{\beta_{*}} \mu_{\pi} / \lambda^{1 / 2}+Z_{S} / \lambda^{1 / 2}\right)^{\prime}\left(\operatorname{sgn}\left(d_{\beta_{*}}\right) \mu_{\pi}+O_{a . s .}\left(1 / \mid d_{\beta_{*}}\right)\right)}{\left(1+o_{a . s .}(1)\right)} \\
= & \left(\operatorname{sgn}\left(d_{\beta_{*}}\right) \Upsilon^{\prime} Z_{S}+\operatorname{sgn}\left(d_{\beta_{*}}\right) \lambda^{1 / 2} c_{\beta_{*}}+O_{\text {a.s. }}\left(\frac{\left(\lambda c_{\beta_{*}}^{2}\right)^{1 / 2}}{\left(\lambda d_{\beta_{*}}^{2}\right)^{1 / 2}}\right)+O_{\text {a.s. }}\left(\frac{1}{\left(\lambda d_{\beta_{*}}^{2}\right)^{1 / 2}}\right)\right) \\
& \times\left(1+o_{a . s .}(1)\right) \\
\rightarrow & \\
= & : \operatorname{LM} M_{1 \infty} \sim N\left(\operatorname{sgn}\left(d_{\beta_{*}}\right) \Upsilon^{\prime} Z_{S}+\operatorname{sgn}\left(d_{\beta_{*}}\right) c_{\infty}, 1\right), \tag{18.5}
\end{align*}
$$

where the first equality holds by (3.1) and (18.4), the second equality holds using $d_{\beta_{*}} \mu_{\pi}+Z_{T}=$ $\left(\lambda d_{\beta_{*}}^{2}\right)^{1 / 2}\left(d_{\beta_{*}} \mu_{\pi} /\left(\lambda d_{\beta_{*}}^{2}\right)^{1 / 2}+o_{\text {a.s. }}(1)\right)$ since $\lambda d_{\beta_{*}}^{2} \rightarrow \infty$, the convergence holds because $\lambda d_{\beta_{*}}^{2} \rightarrow \infty$ and $\lambda^{1 / 2} c_{\beta_{*}} \rightarrow c_{\infty}$, and the limit random variable $L M_{1 \infty}$ has a $N\left(\operatorname{sgn}\left(d_{\beta_{*}}\right) c_{\infty}, 1\right)$ distribution because $\operatorname{sgn}\left(d_{\beta_{*}}\right) \Upsilon^{\prime} Z_{S} \sim N(0,1)$ (since $Z_{S} \sim N\left(0^{k}, I_{k}\right)$ and $\|\Upsilon\|=1$ ).

The a.s. convergence in 18.5 implies convergence in distribution by the dominated convergence theorem applied to $1\left(Q_{S T} / Q_{T}^{1 / 2} \leq y\right)$ for any fixed $y \in R$. In consequence, we have

$$
\begin{equation*}
P\left(L M>\chi_{1,1-\alpha}^{2}\right)=P\left(\left(Q_{S T} / Q_{T}^{1 / 2}\right)^{2}>\chi_{1,1-\alpha}^{2}\right) \rightarrow P\left(L M_{1 \infty}^{2}>\chi_{1,1-\alpha}^{2}\right)=P\left(\chi_{1}^{2}\left(c_{\infty}^{2}\right)>\chi_{1,1-\alpha}^{2}\right) \tag{18.6}
\end{equation*}
$$

as $\lambda d_{\beta_{*}}^{2} \rightarrow \infty$ and $\lambda^{1 / 2} c_{\beta_{*}} \rightarrow c_{\infty}$, which establishes part (c).
To prove Theorem 8.1(a), we apply Lemma 18.1 to a realization of the random vectors $Z_{S}$ and $Z_{T}$ with

$$
\begin{align*}
x & :=\left(\lambda d_{\beta_{*}}^{2} Q_{T}\right)^{1 / 2}, \\
b_{1 x} x & :=\left(\lambda \xi_{\beta_{*}}\left(Q ; \beta_{0}, \Omega\right)\right)^{1 / 2}:=\lambda^{1 / 2}\left(c_{\beta_{*}}^{2} Q_{S}+2 c_{\beta_{*}} d_{\beta_{*}} Q_{S T}+d_{\beta_{*}}^{2} Q_{T}\right)^{1 / 2}, \\
b_{2 x} x & :=\lambda^{1 / 2}\left(c_{\beta_{*}}^{2} Q_{S}-2 c_{\beta_{*}} d_{\beta_{*}} Q_{S T}+d_{\beta_{*}}^{2} Q_{T}\right)^{1 / 2}, \\
K_{11 x} & :=\left(b_{1 x} x\right)^{-(k-1) / 2}, \\
K_{12 x} & :=\frac{\left(b_{1 x} x\right)^{1 / 2} I_{(k-2) / 2}\left(b_{1 x} x\right)}{e^{b_{1 x} x}} \\
K_{21 x} & :=\left(b_{2 x} x\right)^{-(k-1) / 2}, \text { and } \\
K_{22 x} & :=\frac{\left(b_{2 x} x\right)^{1 / 2} I_{(k-2) / 2}\left(b_{2 x} x\right)}{e^{b_{2 x} x}}, \tag{18.7}
\end{align*}
$$

Thus, we take $\eta:=-(k-1) / 2$.
We have

$$
\begin{equation*}
Q_{T}=\left(d_{\beta_{*}} \mu_{\pi}+Z_{T}\right)^{\prime}\left(d_{\beta_{*}} \mu_{\pi}+Z_{T}\right)=\lambda d_{\beta_{*}}^{2}\left(1+o_{a . s .}(1)\right) \tag{18.8}
\end{equation*}
$$

This implies that $x=\left(\lambda d_{\beta_{*}}^{2}\right)\left(1+o_{\text {a.s. }}(1)\right)$. Thus, $x \rightarrow \infty$ a.s. since $\lambda d_{\beta_{*}}^{2} \rightarrow \infty$ by assumption.
The conditions $\lambda d_{\beta_{*}}^{2} \rightarrow \infty$ and $\lambda^{1 / 2} c_{\beta_{*}} \rightarrow c_{\infty} \in R$ imply that $b_{1 x} x \rightarrow \infty$ and $b_{2 x} x \rightarrow \infty$ as $x \rightarrow \infty$. In consequence, by the properties of the modified Bessel function of the first kind, $I_{(k-2) / 2}(x)$ for $x$ large, e.g., see Lebedev (1965, p. 136),

$$
\begin{equation*}
\lim _{b_{1 x} x \rightarrow \infty} K_{12 x}=1 /(2 \pi)^{1 / 2} \text { and } \lim _{b_{2 x} x \rightarrow \infty} K_{22 x}=1 /(2 \pi)^{1 / 2} \tag{18.9}
\end{equation*}
$$

Hence, the assumptions of Lemma 18.1 on $K_{j 2 x}$ for $j=1,2$ hold with $K_{\infty}=1 /(2 \pi)^{1 / 2}$.
Next, we have

$$
\begin{align*}
b_{1 x} & =\left(\lambda c_{\beta_{*}}^{2} Q_{S}+2 \lambda c_{\beta_{*}} d_{\beta_{*}} Q_{S T}+\lambda d_{\beta_{*}}^{2} Q_{T}\right)^{1 / 2} / x \\
& =\left(1+\frac{2 \lambda c_{\beta_{*}} d_{\beta_{*}} Q_{S T}}{\left(\lambda d_{\beta_{*}}^{2} Q_{T}\right)^{1 / 2} x}+\frac{\lambda c_{\beta_{*}}^{2} Q_{S}}{x^{2}}\right)^{1 / 2} \\
& =\left(1+\frac{2 \lambda^{1 / 2} c_{\beta_{*}} \operatorname{sgn}\left(d_{\beta_{*}}\right)}{x} \frac{Q_{S T}}{\left.Q_{T}^{1 / 2}+\frac{\lambda c_{\beta_{*}}^{2} Q_{S}}{x^{2}}\right)^{1 / 2}}\right. \\
& =1+\left(1+o_{a . s .}(1)\right)^{-1 / 2}\left(\frac{2 \lambda^{1 / 2} c_{\beta_{*}} \operatorname{sgn}\left(d_{\beta_{*}}\right)}{x} \frac{Q_{S T}}{Q_{T}^{1 / 2}}+\frac{\lambda c_{\beta_{*}}^{2} Q_{S}}{x^{2}}\right) \tag{18.10}
\end{align*}
$$

where the fourth equality holds by the mean value theorem because $\lambda^{1 / 2} c_{\beta_{*}}=O(1), x \rightarrow \infty$ a.s., and $Q_{S T} / Q_{T}^{1 / 2}=O(1)$ a.s. (by 18.5 ) imply that the term in parentheses on the last line of 18.10 ) is $o_{\text {a.s. }}$ (1).

From 18.10, we have

$$
\begin{align*}
\delta_{x} & =\left(1+o_{\text {a.s. }}(1)\right)^{-1 / 2}\left(2 \lambda^{1 / 2} c_{\beta_{*}} \operatorname{sgn}\left(d_{\beta_{*}}\right) \frac{Q_{S T}}{Q_{T}^{1 / 2}}+\frac{\lambda c_{\beta_{*}}^{2} Q_{S}}{x}\right) \\
& \rightarrow 2 c_{\infty} \operatorname{sgn}\left(d_{\beta_{*}}\right) L M_{1 \infty}=: \delta_{\infty} \text { a.s. } \tag{18.11}
\end{align*}
$$

using (18.5). This verifies the convergence condition of Lemma 18.1 on $\delta_{x}$ with $\delta_{\infty} \neq 0$ a.s. (by the absolute continuity of $Z_{S}$ ). Hence, Lemma 18.1 applies with $x, b_{1 x}, \ldots$ as in (18.7).

Let $\xi_{\beta_{*}}$ abbreviate $\xi_{\beta_{*}}\left(Q ; \beta_{0}, \Omega\right)=c_{\beta_{*}}^{2} Q_{S}+2 c_{\beta_{*}} d_{\beta_{*}} Q_{S T}+d_{\beta_{*}}^{2} Q_{T}$. Let $\xi_{\beta_{2 *}}=c_{\beta_{*}}^{2} Q_{S}-2 c_{\beta_{*}} d_{\beta_{*}} Q_{S T}$ $+d_{\beta_{*}}^{2} Q_{T}$. So, $b_{1 x} x=\left(\lambda \xi_{\beta_{*}}\right)^{1 / 2}$ and $b_{2 x} x=\left(\lambda \xi_{\beta_{2 *}}\right)^{1 / 2}$. Let

$$
\begin{align*}
\tau\left(\beta_{*}, \lambda, Q_{T}\right): & =-\left(\lambda d_{\beta_{*}}^{2} Q_{T}\right)^{1 / 2}+\frac{k-1}{2} \log \left(\left(\lambda d_{\beta_{*}}^{2} Q_{T}\right)^{1 / 2}\right)-\log K_{\infty} \\
& =-x-\eta \log x-\log K_{\infty} \tag{18.12}
\end{align*}
$$

where the equality holds using the definitions in 18.7) and $K_{\infty}=1 /(2 \pi)^{1 / 2}$ by 18.9).
Given the definitions of $\operatorname{POIS2}\left(Q ; \beta_{0}, \beta_{*}, \lambda\right)$ and $x, b_{1 x}, \ldots$ in 12.5) and 18.7), respectively, Lemma 18.1(a) gives

$$
\begin{align*}
& \log \left(\text { POIS } 2\left(Q ; \beta_{0}, \beta_{*}, \lambda\right)\right)+\log \left(2 \psi_{2}\left(Q_{T} ; \beta_{0}, \beta_{*}, \lambda\right)\right)+\tau\left(\beta_{*}, \lambda, Q_{T}\right) \\
= & \log \left(\left(\lambda \xi_{\beta_{*}}\right)^{-(k-2) / 4} I_{(k-2) / 2}\left(\left(\lambda \xi_{\beta_{*}}\right)^{1 / 2}\right)+\left(\lambda \xi_{\beta_{2 *}}\right)^{-(k-2) / 4} I_{(k-2) / 2}\left(\left(\lambda \xi_{\beta_{2 *}}\right)^{1 / 2}\right)\right)+\tau\left(\beta_{*}, \lambda, Q_{T}\right) \\
= & \log \left(\left(\lambda \xi_{\beta_{*}}\right)^{-(k-1) / 4} \frac{\left(\lambda \xi_{\beta_{*}}\right)^{1 / 4} I_{(k-2) / 2}\left(\left(\lambda \xi_{\beta_{*}}\right)^{1 / 2}\right)}{e^{\left(\lambda \xi_{\beta_{*}}\right)^{1 / 2}}} e^{\left(\lambda \xi_{\beta_{*}}\right)^{1 / 2}}\right. \\
& \left.\quad+\left(\lambda \xi_{\beta_{2 *}}\right)^{-(k-1) / 4} \frac{\left(\lambda \xi_{\beta_{2 *}}\right)^{1 / 4} I_{(k-2) / 2}\left(\left(\lambda \xi_{\beta_{2 *}}\right)^{1 / 2}\right)}{e^{\left(\lambda \xi_{\left.\beta_{2 *}\right)^{1 / 2}}^{1 / 2}\right.}} e^{\left(\lambda \xi_{\beta_{2 *}}\right)^{1 / 2}}\right)+\tau\left(\beta_{*}, \lambda, Q_{T}\right) \\
= & \log \left(K_{11 x} K_{12 x} e^{b_{1 x} x}+K_{21 x} K_{22 x} e^{b_{2 x} x}\right)-x-\eta \log x-\log K_{\infty} \\
\rightarrow & a . s . \\
= & \delta_{\infty}+\log \left(1+e^{-2 \delta_{\infty}}\right) \\
= & s\left(\delta_{\infty}\right)  \tag{18.13}\\
& \left.s c_{\infty}\left|L M_{1 \infty}\right|\right)
\end{align*}
$$

where $\psi_{2}\left(Q_{T} ; \beta_{0}, \beta_{*}, \lambda\right)$ is defined in 12.5, $L M_{1 \infty}^{2} \sim \chi_{1}^{2}\left(c_{\infty}^{2}\right)$ is defined in 18.5), the first equality holds by the definition of $\operatorname{POIS} 2\left(Q ; \beta_{0}, \beta_{*}, \lambda\right)$ in 12.5 , the third equality uses the definitions in (18.7) and 18.12), the convergence holds by Lemma 18.1(a), the second last equality holds by the definition of $s(y)$ in Lemma 18.1 (b), and the last equality holds because $\delta_{\infty}:=2 c_{\infty} \operatorname{sgn}\left(d_{\beta_{*}}\right) L M_{1 \infty}$, see 18.11), and $s(y)$ is symmetric around zero by Lemma 18.1(b).

Equation 18.13 ) and the dominated convergence theorem (applied to $1\left(\log \left(\operatorname{POIS2}\left(Q ; \beta_{0}, \beta_{*}, \lambda\right)\right)\right.$ $\left.+\log \left(2 \psi_{2}\left(Q_{T} ; \beta_{0}, \beta_{*}, \lambda\right)\right)+\tau\left(\beta_{*}, \lambda, Q_{T}\right) \leq w\right)$ for any $\left.w \in R\right)$ give

$$
\begin{equation*}
\log \left(\operatorname{POIS2}\left(Q ; \beta_{0}, \beta_{*}, \lambda\right)\right)+\log \left(2 \psi_{2}\left(Q_{T} ; \beta_{0}, \beta_{*}, \lambda\right)\right)+\tau\left(\beta_{*}, \lambda, Q_{T}\right) \rightarrow_{d} s\left(\delta_{\infty}\right)=s\left(2 c_{\infty}\left|L M_{1 \infty}\right|\right) . \tag{18.14}
\end{equation*}
$$

Now we consider the behavior of the critical value function for the POIS2 test, $\kappa_{2, \beta_{0}}\left(q_{T}\right)$, where $q_{T}$ denotes a realization of $Q_{T}$. We are interested in the power of the POIS2 test. So, we are interested in the behavior of $\kappa_{2, \beta_{0}}\left(q_{T}\right)$ for $q_{T}$ sequences as $\lambda d_{\beta_{*}}^{2} \rightarrow \infty$ and $\lambda^{1 / 2} c_{\beta_{*}} \rightarrow c_{\infty}$
that are generated when the true parameters are $\left(\beta_{*}, \lambda\right)$. This behavior is given in (18.8) to be $q_{T}=\lambda d_{\beta_{*}}^{2}(1+o(1))$ a.s. under $\left(\beta_{*}, \lambda\right)$.

Up to this point in the proof, the parameters $\left(\beta_{*}, \lambda\right)$ have played a duel role. First, they denote the parameter values against which the POIS2 test is designed to have optimal two-sided power and, hence, determine the form of the POIS2 test statistic. Second, they denote the true values of $\beta$ and $\lambda$ (because we are interested in the power of the POIS2 test when the $\left(\beta_{*}, \lambda\right)$ values for which it is designed are the true values). Here, where we discuss the behavior of the critical value function $\kappa_{2, \beta_{0}}(\cdot),\left(\beta_{*}, \lambda\right)$ only play the former role. The true value of $\beta$ is $\beta_{0}$ and the true value of $\lambda$ we denote by $\lambda_{0}$. The function $\kappa_{2, \beta_{0}}(\cdot)$ depends on $\left(\beta_{*}, \lambda\right)$ because the POIS2 test statistic does, but the null distribution that determines $\kappa_{2, \beta_{0}}(\cdot)$ does not depend on $\left(\beta_{*}, \lambda\right)$. In spite of this, the values $q_{T}$ which are of interest to us, do depend on $\left(\beta_{*}, \lambda\right)$ as noted in the previous paragraph.

The function $\kappa_{2, \beta_{0}}(\cdot)$ is defined in 12.6 . Its definition depends on the conditional null distribution of $Q_{1}$ given $Q_{T}=q_{T}$ whose density $f_{Q_{1} \mid Q_{T}}\left(\cdot \mid q_{T}\right)$ is given in 12.3). This density depends on $k$, but not on any other parameters, such as $\beta_{0}, \lambda_{0}=\mu_{\pi_{0}}^{\prime} \mu_{\pi_{0}}$, or $\Omega$. In consequence, for the purposes of determining the properties of $\kappa_{2, \beta_{0}}(\cdot)$ we can suppose that $\beta_{0}=0, \mu_{\pi_{0}}=1^{k} /\left\|1^{k}\right\|, \lambda_{0}=1$, and $\Omega=I_{2}$. In this case,

$$
\begin{equation*}
S=Z_{S} \sim N\left(0^{k}, I_{k}\right), T=\mu_{\pi_{0}}+Z_{T} \sim N\left(\mu_{\pi_{0}}, I_{k}\right) \tag{18.15}
\end{equation*}
$$

and $S$ and $T$ are independent (using $d_{\beta_{0}}\left(\beta_{0}, \Omega\right)=b_{0}^{\prime} \Omega b_{0}\left(b_{0}^{\prime} \Omega b_{0}\right)^{-1 / 2} \operatorname{det}(\Omega)^{-1 / 2}=1$ since $b_{0}=$ $\left.\left(1, \beta_{0}\right)^{\prime}=(1,0)^{\prime}\right)$.

We now show that $\kappa_{2, \beta_{0}}\left(q_{T}\right)$ satisfies

$$
\begin{equation*}
\log \left(\kappa_{2, \beta_{0}}\left(q_{T}\right)\right)+\log \left(2 \psi_{2}\left(q_{T} ; \beta_{0}, \beta_{*}, \lambda\right)\right)+\tau\left(\beta_{*}, \lambda, q_{T}\right) \rightarrow s\left(2\left|c_{\infty}\right|\left(\chi_{1,1-\alpha}^{2}\right)^{1 / 2}\right) \text { as } q_{T} \rightarrow \infty \tag{18.16}
\end{equation*}
$$

for any sequence of constants $q_{T}=\lambda d_{\beta_{*}}^{2}(1+o(1))$ as $\lambda d_{\beta_{*}}^{2} \rightarrow \infty$.
Suppose random variables $\left\{W_{m}: m \geq 1\right\}$ and $W$ satisfy: (i) $W_{m} \rightarrow_{d} W$ as $m \rightarrow \infty$, (ii) $W$ has a continuous and strictly increasing distribution function at its $1-\alpha$ quantile $\kappa_{\infty}$, and (iii) $P\left(W_{m}>\kappa_{m}\right)=\alpha$ for all $m \geq 1$ for some constants $\left\{\kappa_{m}: m \geq 1\right\}$. Then, $\kappa_{m} \rightarrow \kappa_{\infty}$. This holds because if $\lim \sup _{m \rightarrow \infty} \kappa_{m}>\kappa_{\infty}$, then there is a subsequence $\left\{v_{m}\right\}$ of $\{m\}$ such that $\lim _{m \rightarrow \infty} \kappa_{v_{m}}=\kappa_{\infty+}>\kappa_{\infty}$ and $\alpha=P\left(W_{v_{m}}>\kappa_{v_{m}}\right) \rightarrow P\left(W>\kappa_{\infty+}\right)<P\left(W>\kappa_{\infty}\right)=\alpha$, which is a contradiction, and likewise $\liminf _{m \rightarrow \infty} \kappa_{m}<\kappa_{\infty}$ leads to a contradiction.

We apply the result in the previous paragraph with (a) $\left\{W_{m}: m \geq 1\right\}$ given by $\log \left(\operatorname{POIS2}\left(Q ; \beta_{0}\right.\right.$, $\left.\left.\beta_{*}, \lambda\right)\right)+\log \left(2 \psi_{2}\left(q_{T} ; \beta_{0}, \beta_{*}, \lambda\right)\right)+\tau\left(\beta_{*}, \lambda, q_{T}\right)$ under the null hypothesis and conditional on $T=t$ with $t=1^{k} q_{T}^{1 / 2} / k^{1 / 2}$ for some sequence of constants $q_{T}=\lambda d_{\beta_{*}}^{2}(1+o(1)) \rightarrow \infty$ as $\lambda d_{\beta_{*}}^{2} \rightarrow$
$\infty$, (b) $W=s\left(2 c_{\infty}\left|S^{\prime} 1^{k} / k^{1 / 2}\right|\right)$, where $S^{\prime} 1^{k} / k^{1 / 2} \sim N(0,1)$, (c) $\kappa_{m}$ equal to $\log \left(\kappa_{2, \beta_{0}}\left(q_{T}\right)\right)+$ $\log \left(2 \psi_{2}\left(q_{T} ; \beta_{0}, \beta_{*}, \lambda\right)\right)+\tau\left(\beta_{*}, \lambda, q_{T}\right)$, and (d) $\kappa_{\infty}=s\left(2\left|c_{\infty}\right|\left(\chi_{1,1-\alpha}^{2}\right)^{1 / 2}\right)$.

We need to show conditions (i)-(iii) above hold. Condition (ii) holds straightforwardly for $W$ as in (b) given the normal distribution of $S$, the functional form of $s(y)$, and $c_{\infty} \neq 0$.

By definition of $\kappa_{2, \beta_{0}}\left(q_{T}\right)$, under the null hypothesis, $P_{Q_{1} \mid Q_{T}}\left(\operatorname{POIS2}\left(Q ; \beta_{0}, \beta_{*}, \lambda\right)>\kappa_{2, \beta_{0}}\left(q_{T}\right)\right.$ $\left.\mid q_{T}\right)=\alpha$ for all $q_{T} \geq 0$, see 12.6 . This implies that the invariant POIS2 test is similar. In turn, this implies that under the null hypothesis $\operatorname{P}\left(\operatorname{POIS} 2\left(Q ; \beta_{0}, \beta_{*}, \lambda\right)>\kappa_{2, \beta_{0}}\left(q_{T}\right) \mid T=t\right)=\alpha$ for all $t \in R^{k}$ because Theorem 1 of Moreira (2009) shows that any invariant similar test has null rejection probability $\alpha$ conditional on $T$. This verifies condition (iii) because the log function is monotone and the last two summands of $W_{m}$ and $\kappa_{m}$ defined in (a) and (c) above cancel.

Next, we show that condition (i) holds. Given 18.15 and $t=1^{k} q_{T}^{1 / 2} / k^{1 / 2}$, under the null and conditional on $T=t$, we have

$$
\begin{equation*}
\frac{Q_{S T}}{Q_{T}^{1 / 2}}=\frac{S^{\prime} t}{\left(t^{\prime} t\right)^{1 / 2}}=S^{\prime} 1^{k} / k^{1 / 2} \sim \chi_{1}^{2} \tag{18.17}
\end{equation*}
$$

which does not depend on $\lambda d_{\beta_{*}}^{2}$ or $\lambda^{1 / 2} c_{\beta_{*}}$. Hence, in place of the a.s. convergence result for $Q_{S T} / Q_{T}^{1 / 2}$ as $\lambda d_{\beta_{*}}^{2} \rightarrow \infty$ and $\lambda^{1 / 2} c_{\beta_{*} \rightarrow c_{\infty}}$ in 18.5 , which applies under the alternative hypothesis with true parameters $\left(\beta_{*}, \lambda\right)$, we have $Q_{S T} / Q_{T}^{1 / 2}=S^{\prime} 1^{k} / k^{1 / 2}$ under the null hypothesis for all $\lambda d_{\beta_{*}}^{2}$ and $\lambda^{1 / 2} c_{\beta_{*}}$. Using this in place of 18.5, the unconditional a.s. convergence result in 18.13, established in (18.7)-18.13), goes through as a conditional on $T=t$ a.s. result without any further changes. In consequence, the convergence in distribution result in (18.14) also holds conditional on $T=t$ a.s., but with $s\left(2 c_{\infty}\left|S^{\prime} 1^{k} / k^{1 / 2}\right|\right)$ in place of $s\left(2 c_{\infty}\left|L M_{1 \infty}\right|\right)$. This verifies condition (i).

Given that conditions (i)-(iii) hold, we obtain $\kappa_{m} \rightarrow \kappa_{\infty}$ as $\lambda d_{\beta_{*}}^{2} \rightarrow \infty$ for $\kappa_{m}$ and $\kappa_{\infty}$ defined in (c) and (d), respectively, above. This establishes 18.16).

Given 18.16, we have

$$
\begin{align*}
& P_{\beta_{*}, \beta_{0}, \lambda, \Omega}\left(\text { POIS2 }\left(Q ; \beta_{0}, \beta_{*}, \lambda\right)>\kappa_{2, \beta_{0}}\left(Q_{T}\right)\right) \\
= & P_{\beta_{*}, \beta_{0}, \lambda, \Omega}\left(\log \left(\text { POIS } 2\left(Q ; \beta_{0}, \beta_{*}, \lambda\right)\right)+\log \left(2 \psi_{2}\left(Q_{T} ; \beta_{0}, \beta_{*}, \lambda\right)\right)+\tau\left(\beta_{*}, \lambda, Q_{T}\right)\right. \\
& \left.>\log \left(\kappa_{2, \beta_{0}}\left(Q_{T}\right)\right)+\log \left(2 \psi_{2}\left(Q_{T} ; \beta_{0}, \beta_{*}, \lambda\right)\right)+\tau\left(\beta_{*}, \lambda, Q_{T}\right)\right) \\
\rightarrow & { }_{d} P\left(s\left(2 c_{\infty}\left|L M_{1 \infty}\right|\right)>s\left(2 c_{\infty}\left|\chi_{1,1-\alpha}^{2}\right|\right)\right) \\
= & P\left(L M_{1 \infty}^{2}>\chi_{1,1-\alpha}^{2}\right) \\
= & P\left(\chi_{1}^{2}\left(c_{\infty}^{2}\right)>\chi_{1,1-\alpha}^{2}\right), \tag{18.18}
\end{align*}
$$

where the second last equality uses the fact that $s(y)$ is symmetric and strictly increasing for $y>0$ by Lemma 18.1(b). Equation 18.18) establishes part (a) of the theorem.

Now we establish part (b) of the theorem. Let

$$
\begin{equation*}
J:=S^{\prime} M_{T} S \tag{18.19}
\end{equation*}
$$

where $M_{T}:=I_{k}-P_{T}$ and $P_{T}:=T\left(T^{\prime} T\right)^{-1} T^{\prime}$. It follows from (3.3) that

$$
\begin{equation*}
L M=S^{\prime} P_{T} S \text { and } Q_{S}=L M+J \tag{18.20}
\end{equation*}
$$

By 18.8,,$Q_{T}=\lambda d_{\beta_{*}}^{2}\left(1+o_{\text {a.s. }}(1)\right) \rightarrow \infty$ a.s. as $\lambda d_{\beta_{*}}^{2} \rightarrow \infty$ when the true parameters are $\left(\beta_{*}, \lambda\right)$. By 18.20 and some algebra, we have $\left(Q_{S}-Q_{T}\right)^{2}+4 L M \cdot Q_{T}=\left(L M-J+Q_{T}\right)^{2}+4 L M \cdot J$. This and the definition of $L R$ in (3.3) give

$$
\begin{equation*}
L R=\frac{1}{2}\left(L M+J-Q_{T}+\sqrt{\left(L M-J+Q_{T}\right)^{2}+4 L M \cdot J}\right) . \tag{18.21}
\end{equation*}
$$

Using a mean-value expansion of the square-root expression in 18.21) about $\left(L M-J+Q_{T}\right)^{2}$, we have

$$
\begin{equation*}
\sqrt{\left(L M-J+Q_{T}\right)^{2}+4 L M \cdot J}=L M-J+Q_{T}+(2 \sqrt{\zeta})^{-1} 4 L M \cdot J \tag{18.22}
\end{equation*}
$$

for an intermediate value $\zeta$ between $\left(L M-J+Q_{T}\right)^{2}$ and $\left(L M-J+Q_{T}\right)^{2}+4 L M \cdot J$. It follows that

$$
\begin{equation*}
L R=L M+o(1) \text { a.s. } \tag{18.23}
\end{equation*}
$$

because $Q_{T} \rightarrow \infty$ a.s., $L M=O(1)$ a.s., and $J=O(1)$ a.s. as $\lambda d_{\beta_{*}}^{2} \rightarrow \infty$ and $\lambda^{1 / 2} c_{\beta_{*}} \rightarrow c_{\infty} \in R$, which imply that $(\sqrt{\zeta})^{-1}=o(1)$ a.s. These properties of $L M$ and $J$ hold because $L M=S^{\prime} P_{T} S \leq$ $S^{\prime} S, J=S^{\prime} M_{T} S \leq S^{\prime} S$, and, using (18.4), we have $S^{\prime} S=\left(c_{\beta_{*}} \mu_{\pi}+Z_{S}\right)^{\prime}\left(c_{\beta_{*}} \mu_{\pi}+Z_{S}\right)=O(1)$ a.s. because $\left\|c_{\beta_{*}} \mu_{\pi}\right\|^{2}=\lambda c_{\beta_{*}}^{2}=O(1)$ by assumption.

The critical value function for the CLR test, $\kappa_{L R, \alpha}(\cdot)$, depends only on $k$ and $\alpha$, see Lemma $3(\mathrm{c})$ and (3.5) in AMS. It is well known in the literature that $\kappa_{L R, \alpha}(\cdot)$ satisfies $\kappa_{L R, \alpha}\left(q_{T}\right) \rightarrow \chi_{1,1-\alpha}^{2}$ as $q_{T} \rightarrow \infty$, e.g., see Moreira (2003, Proposition 1). Hence, we have

$$
\begin{align*}
& P_{\beta_{*}, \beta_{0}, \lambda, \Omega}\left(L R>\kappa_{L R, \alpha}\left(Q_{T}\right)\right)=P_{\beta_{*}, \beta_{0}, \lambda, \Omega}\left(L M+o_{a . s .}(1)>\chi_{1,1-\alpha}^{2}+o_{a . s .}(1)\right) \\
= & P_{\beta_{*}, \beta_{0}, \lambda, \Omega}\left(L M+o_{p}(1)>\chi_{1,1-\alpha}^{2}\right) \rightarrow P\left(\chi_{1}^{2}\left(c_{\infty}^{2}\right)>\chi_{1,1-\alpha}^{2}\right) \tag{18.24}
\end{align*}
$$

as $\lambda d_{\beta_{*}}^{2} \rightarrow \infty$ and $\lambda^{1 / 2} c_{\beta_{*}} \rightarrow c_{\infty}$, where the first equality holds by $18.23, Q_{T} \rightarrow \infty$ a.s. by 18.8), and $\lim _{q_{T} \rightarrow \infty} \kappa_{L R, \alpha}\left(q_{T}\right)=\chi_{1,1-\alpha}^{2}$ and the convergence holds by part (c) of the theorem. This establishes part (b) of the theorem.

Proof of Theorem 8.2. First, we establish part (a)(i) of the theorem. By (12.8) with $\beta=\beta_{*}$ and $\Sigma=\Sigma_{*}$, we have

$$
\Omega\left(\beta_{*}, \Sigma_{*}\right)=\left[\begin{array}{cc}
\omega_{1}^{2} & \omega_{12}  \tag{18.25}\\
\omega_{12} & \omega_{2}^{2}
\end{array}\right]=\left[\begin{array}{cc}
\sigma_{u}^{2}+2 \sigma_{u v} \beta_{*}+\sigma_{v}^{2} \beta_{*}^{2} & \sigma_{u v}+\sigma_{v}^{2} \beta_{*} \\
\sigma_{u v}+\sigma_{v}^{2} \beta_{*} & \sigma_{v}^{2}
\end{array}\right] .
$$

Using this, we obtain, as $\rho_{u v} \rightarrow \pm 1$,

$$
\begin{align*}
c_{\beta_{*}}=c_{\beta_{*}}\left(\beta_{0}, \Omega\left(\beta_{*}, \Sigma_{*}\right)\right) & =\left(\beta_{*}-\beta_{0}\right)\left(\omega_{1}^{2}-2 \beta_{0} \omega_{12}+\omega_{2}^{2} \beta_{0}^{2}\right)^{-1 / 2} \\
& =\left(\beta_{*}-\beta_{0}\right)\left(\sigma_{u}^{2}+2 \sigma_{u v} \beta_{*}+\sigma_{v}^{2} \beta_{*}^{2}-2 \beta_{0}\left(\sigma_{u v}+\sigma_{v}^{2} \beta_{*}\right)+\sigma_{v}^{2} \beta_{0}^{2}\right)^{-1 / 2} \\
& =\left(\beta_{*}-\beta_{0}\right)\left(\sigma_{u}^{2}+2\left(\beta_{*}-\beta_{0}\right) \sigma_{u} \sigma_{v} \rho_{u v}+\left(\beta_{*}-\beta_{0}\right)^{2} \sigma_{v}^{2}\right)^{-1 / 2} \\
& \rightarrow\left(\beta_{*}-\beta_{0}\right)\left(\sigma_{u}^{2} \pm 2\left(\beta_{*}-\beta_{0}\right) \sigma_{u} \sigma_{v}+\left(\beta_{*}-\beta_{0}\right)^{2} \sigma_{v}^{2}\right)^{-1 / 2} \\
& =\left(\beta_{*}-\beta_{0}\right) /\left|\sigma_{u} \pm\left(\beta_{*}-\beta_{0}\right) \sigma_{v}\right| \tag{18.26}
\end{align*}
$$

where the second equality uses (2.3), the convergence only holds if $\sigma_{u} \pm\left(\beta_{*}-\beta_{0}\right) \sigma_{v} \neq 0$, and the fourth equality uses $\sigma_{u v}=\sigma_{u} \sigma_{v} \rho_{u v}$. This proves part (a)(i).

To prove part (a)(ii), we have

$$
\begin{align*}
d_{\beta_{*}} & =d_{\beta_{*}}\left(\beta_{0}, \Omega\left(\beta_{*}, \Sigma_{*}\right)\right)=b_{*}^{\prime} \Omega b_{0}\left(b_{0}^{\prime} \Omega b_{0}\right)^{-1 / 2} \operatorname{det}(\Omega)^{-1 / 2}  \tag{18.27}\\
& =\left(\omega_{1}^{2}-\omega_{12}\left(\beta_{0}+\beta_{*}\right)+\omega_{2}^{2} \beta_{0} \beta_{*}\right) \cdot\left(\omega_{1}^{2}-2 \beta_{0} \omega_{12}+\omega_{2}^{2} \beta_{0}^{2}\right)^{-1 / 2} \cdot\left(\omega_{1}^{2} \omega_{2}^{2}-\omega_{12}^{2}\right)^{-1 / 2}
\end{align*}
$$

where the second equality holds by (2.3). The second multiplicand on the rhs of 18.27) converges to $\left|\sigma_{u} \pm\left(\beta_{*}-\beta_{0}\right) \sigma_{v}\right|^{-1}$ provided $\sigma_{u} \pm\left(\beta_{*}-\beta_{0}\right) \sigma_{v} \neq 0$ by the calculations in 18.26).

The first multiplicand on the rhs of (18.27) satisfies, as $\rho_{u v} \rightarrow \pm 1$,

$$
\begin{align*}
& \omega_{1}^{2}-\omega_{12}\left(\beta_{0}+\beta_{*}\right)+\omega_{2}^{2} \beta_{0} \beta_{*} \\
= & \sigma_{u}^{2}+2 \sigma_{u v} \beta_{*}+\sigma_{v}^{2} \beta_{*}^{2}-\left(\sigma_{u v}+\sigma_{v}^{2} \beta_{*}\right)\left(\beta_{0}+\beta_{*}\right)+\sigma_{v}^{2} \beta_{0} \beta_{*} \\
= & \sigma_{u}^{2}+\sigma_{u} \sigma_{v} \rho_{u v}\left(\beta_{*}-\beta_{0}\right) \\
\rightarrow & \sigma_{u}\left(\sigma_{u} \pm \sigma_{v}\left(\beta_{*}-\beta_{0}\right)\right), \tag{18.28}
\end{align*}
$$

where the first equality uses 18.25 and the second equality holds by simple algebra and $\sigma_{u v}=$ $\sigma_{u} \sigma_{v} \rho_{u v}$.

The reciprocal of the square of the third multiplicand on the rhs of (18.27) satisfies, as $\rho_{u v} \rightarrow \pm 1$,

$$
\begin{align*}
\omega_{1}^{2} \omega_{2}^{2}-\omega_{12}^{2} & =\left(\sigma_{u}^{2}+2 \sigma_{u} \sigma_{v} \rho_{u v} \beta_{*}+\sigma_{v}^{2} \beta_{*}^{2}\right) \sigma_{v}^{2}-\left(\sigma_{u} \sigma_{v} \rho_{u v}+\sigma_{v}^{2} \beta_{*}\right)^{2} \\
& \rightarrow\left(\sigma_{u}^{2} \pm 2 \sigma_{u} \sigma_{v} \beta_{*}+\sigma_{v}^{2} \beta_{*}^{2}\right) \sigma_{v}^{2}-\left( \pm \sigma_{u} \sigma_{v}+\sigma_{v}^{2} \beta_{*}\right)^{2} \\
& =\left(\sigma_{u} \pm \sigma_{v} \beta_{*}\right)^{2} \sigma_{v}^{2}-\left( \pm \sigma_{u}+\sigma_{v} \beta_{*}\right)^{2} \sigma_{v}^{2} \\
& =0, \tag{18.29}
\end{align*}
$$

where the first equality holds by 18.25 and $\sigma_{u v}=\sigma_{u} \sigma_{v} \rho_{u v}$.
Combining 18.27)-18.29) and $\lambda>0$ proves part (a)(ii).
Next, we establish part (b) of the theorem. Using the definition of $c_{\beta}\left(\beta_{0}, \Omega\right)$ in (2.3), we have

$$
\begin{align*}
\lim _{\rho_{\Omega} \rightarrow \pm 1} c_{\beta_{*}}\left(\beta_{0}, \Omega\right) & =\lim _{\rho_{\Omega} \rightarrow \pm 1}\left(\beta_{*}-\beta_{0}\right)\left(b_{0}^{\prime} \Omega b_{0}\right)^{-1 / 2} \\
& =\lim _{\rho_{\Omega} \rightarrow \pm 1}\left(\beta_{*}-\beta_{0}\right)\left(\omega_{1}^{2}-2 \beta_{0} \omega_{1} \omega_{2} \rho_{\Omega}+\omega_{2}^{2} \beta_{0}^{2}\right)^{-1 / 2} \\
& =\left(\beta_{*}-\beta_{0}\right) /\left|\omega_{1} \mp \omega_{2} \beta_{0}\right|, \tag{18.30}
\end{align*}
$$

where the third equality holds provided $\omega_{1} \mp \omega_{2} \beta_{0} \neq 0$. This establishes part (b)(i) of the theorem.
Using the definition of $d_{\beta}\left(\beta_{0}, \Omega\right)$ in $(2.3)$ and $b_{*}:=\left(1, \beta_{*}\right)^{\prime}$, we have

$$
\begin{align*}
\lim _{\rho_{\Omega} \rightarrow \pm 1} d_{\beta_{*}}\left(\beta_{0}, \Omega\right)= & \lim _{\rho_{\Omega} \rightarrow \pm 1} b_{*}^{\prime} \Omega b_{0}\left(b_{0}^{\prime} \Omega b_{0}\right)^{-1 / 2} \operatorname{det}(\Omega)^{-1 / 2} \\
= & \lim _{\rho_{\Omega} \rightarrow \pm 1}\left(\omega_{1}^{2}-\omega_{1} \omega_{2} \rho_{\Omega}\left(\beta_{0}+\beta_{*}\right)+\omega_{2}^{2} \beta_{0} \beta_{*}\right) \cdot\left(\omega_{1}^{2}-2 \beta_{0} \omega_{1} \omega_{2} \rho_{\Omega}+\omega_{2}^{2} \beta_{0}^{2}\right)^{-1 / 2} \\
& \cdot\left(\omega_{1}^{2} \omega_{2}^{2}-\omega_{1}^{2} \omega_{2}^{2} \rho_{\Omega}^{2}\right)^{-1 / 2} \\
= & \left(\omega_{1} \mp \omega_{2} \beta_{0}\right)\left(\omega_{1} \mp \omega_{2} \beta_{*}\right) \cdot \frac{1}{\left|\omega_{1} \mp \omega_{2} \beta_{0}\right|} \cdot \frac{1}{\omega_{1} \omega_{2}} \cdot \lim _{\rho_{\Omega} \rightarrow \pm 1} \frac{1}{\left(1-\rho_{\Omega}^{2}\right)^{1 / 2}} \\
= & \operatorname{sgn}\left(\left(\omega_{1} \mp \omega_{2} \beta_{0}\right)\left(\omega_{1} \mp \omega_{2} \beta_{*}\right)\right) \cdot \infty, \tag{18.31}
\end{align*}
$$

where the third and fourth equalities hold provided $\omega_{1} \mp \omega_{2} \beta_{0} \neq 0$ and $\omega_{1} \mp \omega_{2} \beta_{*} \neq 0$. This and $\lambda>0$ establish part (b)(ii) of the theorem.

Part (c)(i) is proved as follows:

$$
\begin{equation*}
c_{\beta_{*}}=\frac{\beta_{*}-\beta_{0}}{\left(\sigma_{u}^{2}+2\left(\beta_{*}-\beta_{0}\right) \sigma_{u} \sigma_{v} \rho_{u v}+\left(\beta_{*}-\beta_{0}\right)^{2} \sigma_{v}^{2}\right)^{1 / 2}} \rightarrow \mp \frac{1}{\sigma_{v}} \text { as }\left(\rho_{u v}, \beta_{0}\right) \rightarrow(1, \pm \infty) \tag{18.32}
\end{equation*}
$$

where the first equality holds by $\sqrt{18.26}$ ) and the convergence holds by considering only the dominant $\beta_{0}$ terms. The same result holds as $\left(\rho_{u v}, \beta_{0}\right) \rightarrow(1, \pm \infty)$ because $\rho_{u v}$ enters the middle expression
in (18.32) only through a term that does not affect the limit.
Part (c)(ii) is proved using the expression for $d_{\beta_{*}}$ in 18.27). By 18.29, the third multiplicand in 18.27), which does not depend on $\beta_{0}$, diverges to infinity when $\rho_{u v} \rightarrow 1$ or -1 . The product of the first two multiplicands on the rhs of (18.27) equals

$$
\begin{align*}
\frac{\omega_{1}^{2}-\omega_{12}\left(\beta_{0}+\beta_{*}\right)+\omega_{2}^{2} \beta_{0} \beta_{*}}{\left(\omega_{1}^{2}-2 \beta_{0} \omega_{12}+\omega_{2}^{2} \beta_{0}^{2}\right)^{1 / 2}} & =\frac{\sigma_{u}^{2}+\sigma_{u} \sigma_{v} \rho_{u v}\left(\beta_{*}-\beta_{0}\right)}{\left(\sigma_{u}^{2}+2\left(\beta_{*}-\beta_{0}\right) \sigma_{u} \sigma_{v} \rho_{u v}+\left(\beta_{*}-\beta_{0}\right)^{2} \sigma_{v}^{2}\right)^{1 / 2}} \\
& \rightarrow \mp \frac{\sigma_{u} \sigma_{v}}{\sigma_{v}}=\mp \sigma_{u} \text { as }\left(\rho_{u v}, \beta_{0}\right) \rightarrow(1, \pm \infty), \tag{18.33}
\end{align*}
$$

where the equality uses the calculations in the first three lines of 18.26 and 18.28 and the convergence holds by considering only the dominant $\beta_{0}$ terms. When $\left(\rho_{u v}, \beta_{0}\right) \rightarrow(-1, \pm \infty)$, the limit in (18.33) is $\pm \sigma_{u}$ because $\rho_{u v}$ enters multiplicatively in the dominant $\beta_{0}$ term in the numerator. In both cases, the product of the first two multiplicands on the rhs of 18.27) converges to a nonzero constant and the third multiplicand diverges to infinity. Hence, $d_{\beta_{*}}$ diverges to $+\infty$ or $-\infty$ and $\lambda d_{\beta_{*}}^{2} \rightarrow \infty$ since $\lambda>0$, which completes the proof.

Part (d)(i) holds because

$$
\begin{equation*}
c_{\beta_{*}}=\frac{\beta_{*}-\beta_{0}}{\left(\omega_{1}^{2}-2 \beta_{0} \omega_{1} \omega_{2} \rho_{\Omega}+\omega_{2}^{2} \beta_{0}^{2}\right)^{1 / 2}} \rightarrow \mp \frac{1}{\omega_{2}} \text { as }\left(\rho_{\Omega}, \beta_{0}\right) \rightarrow(1, \pm \infty), \tag{18.34}
\end{equation*}
$$

where the equality uses 18.30 . The same convergence holds as $\left(\rho_{\Omega}, \beta_{0}\right) \rightarrow(1, \pm \infty)$ because $\rho_{u v}$ enters the middle expression in (18.34) only through a term that does not affect the limit.

Part (d)(ii) is proved using the expression for $d_{\beta_{*}}$ in 18.31):

$$
\begin{align*}
& d_{\beta_{*}}=\frac{\left(\omega_{1}^{2}-\omega_{1} \omega_{2} \rho_{\Omega}\left(\beta_{0}+\beta_{*}\right)+\omega_{2}^{2} \beta_{0} \beta_{*}\right)}{\left(\omega_{1}^{2}-2 \beta_{0} \omega_{1} \omega_{2} \rho_{\Omega}+\omega_{2}^{2} \beta_{0}^{2}\right)^{1 / 2}} \cdot\left(\omega_{1}^{2} \omega_{2}^{2}-\omega_{1}^{2} \omega_{2}^{2} \rho_{\Omega}^{2}\right)^{-1 / 2}, \\
& \frac{\left(\omega_{1}^{2}-\omega_{1} \omega_{2} \rho_{\Omega}\left(\beta_{0}+\beta_{*}\right)+\omega_{2}^{2} \beta_{0} \beta_{*}\right)}{\left(\omega_{1}^{2}-2 \beta_{0} \omega_{1} \omega_{2} \rho_{\Omega}+\omega_{2}^{2} \beta_{0}^{2}\right)^{1 / 2}} \rightarrow \frac{ \pm\left(\omega_{2}^{2} \beta_{*}-\omega_{1} \omega_{2}\right)}{\omega_{2}}=\mp\left(\omega_{1}-\omega_{2} \beta_{*}\right), \text { and } \\
& \left(\omega_{1}^{2} \omega_{2}^{2}-\omega_{1}^{2} \omega_{2}^{2} \rho_{\Omega}^{2}\right)^{-1 / 2} \rightarrow \infty \text { as }\left(\rho_{\Omega}, \beta_{0}\right) \rightarrow(1, \pm \infty) . \tag{18.35}
\end{align*}
$$

Hence, $\lambda d_{\beta_{*}}^{2} \rightarrow \infty$ as $\left(\rho_{\Omega}, \beta_{0}\right) \rightarrow(1, \pm \infty)$ provided $\omega_{1}-\omega_{2} \beta_{*} \neq 0$. When $\left(\rho_{\Omega}, \beta_{0}\right) \rightarrow(-1, \pm \infty)$, the limit in the second line of 18.35 is $\pm\left(\omega_{2}^{2} \beta_{*}+\omega_{1} \omega_{2}\right) / \omega_{2}= \pm\left(\omega_{1}+\omega_{2} \beta_{*}\right)$ and, hence, $\lambda d_{\beta_{*}}^{2} \rightarrow \infty$ provided $\omega_{1}+\omega_{2} \beta_{*} \neq 0$, which completes the proof.

## 19 Proofs of Theorem 13.1 and Lemmas 14.1 and 14.2

Proof of Theorem 13.1. By Cor. 2 and Comment 2 to Cor. 2 of Andrews, Moreira, and Stock (2004), for all $\left(\beta_{*}, \beta_{0}, \lambda, \Omega\right)$,

$$
\begin{equation*}
P_{\beta_{*}, \beta_{0}, \lambda, \Omega}\left(\phi_{\beta_{0}}(Q)=1\right) \leq P_{\beta_{*}, \beta_{0}, \lambda, \Omega}\left(\operatorname{POIS}\left(Q ; \beta_{0}, \beta_{*}\right)>\kappa_{\beta_{0}}\left(Q_{T}\right)\right) . \tag{19.1}
\end{equation*}
$$

That is, the test on the rhs is the (one-sided) POIS test for testing $H_{0}: \beta=\beta_{0}$ versus $H_{1}: \beta=\beta_{*}$ for fixed known $\Omega$ and any $\lambda \geq 0$ under $H_{1}$.

We use the dominated convergence theorem (DCT) to show

$$
\begin{equation*}
\lim _{\beta_{0} \rightarrow \pm \infty} P_{\beta_{*}, \beta_{0}, \lambda, \Omega}\left(\operatorname{POIS}\left(Q ; \beta_{0}, \beta_{*}\right)>\kappa_{\beta_{0}}\left(Q_{T}\right)\right)=P_{\rho_{u v}, \lambda_{v}}\left(\operatorname{POIS}\left(Q ; \infty, \rho_{u v}\right)>\kappa_{\infty}\left(Q_{T}\right)\right) . \tag{19.2}
\end{equation*}
$$

Equations 19.1 and 19.2 imply that the result of Theorem 13.1 holds.
By (13.2), 13.5), and Lemma 15.1(b) and (e),

$$
\begin{equation*}
\lim _{\beta_{0} \rightarrow \pm \infty} \operatorname{POIS}\left(q ; \beta_{0}, \beta_{*}\right)=\operatorname{POIS}\left(q ; \infty, \rho_{u v}\right) \tag{19.3}
\end{equation*}
$$

for all $2 \times 2$ variance matrices $q$, for given $\left(\beta_{*}, \pi, \Omega\right)$.
The proof of 19.2 ) is the same as the proof of Lemma 17.1(a), but with $\operatorname{POIS}\left(Q ; \beta_{0}, \beta_{*}\right)$, $\kappa_{\beta_{0}}\left(Q_{T}\right), \operatorname{POIS}\left(Q ; \infty, \rho_{u v}\right)$, and $\kappa_{\infty}\left(Q_{T}\right)$ in place of $\operatorname{POIS} 2\left(Q ; \beta_{0}, \beta_{*}, \lambda\right), \kappa_{2, \beta_{0}}\left(Q_{T}\right), \operatorname{POIS2}(Q ; \infty$, $\left.\left|\rho_{u v}\right|, \lambda_{v}\right)$, and $\kappa_{2, \infty}\left(Q_{T}\right)$, respectively, using 19.3) in place of 17.6), and using the results (established below) that (i) the Lebesgue measure of the set of $\left(q_{S}, q_{S T}, q_{T}\right)$ for which $\operatorname{POIS}\left(q ; \infty, \rho_{u v}\right)=$ $\kappa_{\infty}\left(q_{T}\right)$ is zero, (ii) $P_{Q_{1} \mid Q_{T}}\left(\operatorname{POIS}\left(Q ; \infty, \rho_{u v}\right)=x \mid q_{T}\right)=0$ for all $q_{T} \geq 0$, and (iii) the distribution function of $\operatorname{POIS}\left(Q ; \infty, \rho_{u v}\right)$ is strictly increasing at its $1-\alpha$ quantile $\kappa_{\infty}\left(q_{T}\right)$ under $P_{Q_{1} \mid Q_{T}}\left(\cdot \mid q_{T}\right)$ for all $q_{T} \geq 0$.

Condition (i) holds because (a) $\operatorname{POIS}\left(q ; \infty, \rho_{u v}\right)=q_{S}+2 r_{u v} q_{S T}$ (see 13.5) implies that the Lebesgue measure of the set of $\left(q_{S}, q_{S T}\right)$ for which $q_{S}+2 r_{u v} q_{S T}=\kappa_{\infty}\left(q_{T}\right)$ is zero for all $q_{T}$ and (b) the Lebesgue measure of the set of $\left(q_{S}, q_{S T}, q_{T}\right)$ for which $q_{S}+2 r_{u v} q_{S T}=\kappa_{\infty}\left(q_{T}\right)$ is obtained by integrating the set in (a) over $q_{T} \in R$ subject to the constraint that $q$ is positive definite.

Condition (ii) holds by the absolute continuity of $\operatorname{POIS}\left(Q ; \infty, \rho_{u v}\right)$ under $P_{Q_{1} \mid Q_{T}}\left(\cdot \mid q_{T}\right)$ (by the functional form of $\operatorname{POIS}\left(Q ; \infty, \rho_{u v}\right)$ and the absolute continuity of $Q_{1}$ under $P_{Q_{1} \mid Q_{T}}\left(\cdot \mid q_{T}\right)$, whose density is given in (12.3).

Condition (iii) holds because we can write $\operatorname{POIS}\left(Q ; \infty, \rho_{u v}\right)=S^{\prime} S+2 r_{u v} S^{\prime} T=\left(S+r_{u v} T\right)^{\prime}(S+$ $\left.r_{u v} T\right)-r_{u v}^{2} T^{\prime} T$, where $[S: T]$ has a multivariate normal distribution with means matrix given by (6.2) and identity variance matrix and, hence, $\operatorname{POIS}\left(Q ; \infty, \rho_{u v}\right)$ has a shifted noncentral $\chi^{2}$ distri-
bution conditional on $T=t$. In consequence, it has a positive density on $\left(r_{u v}^{2} t^{\prime} t, \infty\right)=\left(r_{u v}^{2} q_{T}, \infty\right)$ conditional on $T=t$ and also conditional on $Q_{T}=q_{T}$ (because the latter conditional density is the integral of the former conditional density over $t$ such that $\left.t^{\prime} t=q_{T}\right)$. This completes the proof.

Proof of Lemma 14.1. First, we show that (14.4) implies the equation for $\lambda_{2}$ in (14.2). By the expression $d_{\beta}=a^{\prime} \Omega^{-1} a_{0}\left(a_{0}^{\prime} \Omega^{-1} a_{0}\right)^{-1 / 2}$ given in (2.7) in AMS, where $a:=(\beta, 1)^{\prime}$ and $a_{0}:=\left(\beta_{0}, 1\right)^{\prime}$, for any $\beta \in R$,

$$
\begin{align*}
d_{\beta}-d_{\beta_{0}} & =\left(a-a_{0}\right)^{\prime} \Omega^{-1} a_{0}\left(a_{0}^{\prime} \Omega^{-1} a_{0}\right)^{-1 / 2} \\
& =\left(\beta-\beta_{0}\right) e_{1}^{\prime} \Omega^{-1} a_{0}\left(a_{0}^{\prime} \Omega^{-1} a_{0}\right)^{-1 / 2}:=\left(\beta-\beta_{0}\right) r_{\beta_{0}}, \tag{19.4}
\end{align*}
$$

where $e_{1}:=(1,0)^{\prime}$ and the last equality holds by the definition of $r_{\beta_{0}}$.
Substituting (19.4) into the second equation in (14.4) gives

$$
\begin{align*}
& \quad \lambda_{2}^{1 / 2} d_{\beta_{2 *}}= \pm \lambda^{1 / 2} d_{\beta_{*}} \\
& \text { iff } \lambda_{2}^{1 / 2}\left(d_{\beta_{0}}+r_{\beta_{0}}\left(\beta_{2 *}-\beta_{0}\right)\right)= \pm \lambda^{1 / 2}\left(d_{\beta_{0}}+r_{\beta_{0}}\left(\beta_{*}-\beta_{0}\right)\right) \\
& \text { iff } \lambda_{2}^{1 / 2} d_{\beta_{0}}= \pm \lambda^{1 / 2}\left(d_{\beta_{0}}+r_{\beta_{0}}\left(\beta_{*}-\beta_{0}\right)\right)-r_{\beta_{0}} \lambda_{2}^{1 / 2}\left(\beta_{2 *}-\beta_{0}\right) . \tag{19.5}
\end{align*}
$$

Given the definition of $c_{\beta}$ in (2.3), the first equation in (14.4) can be written as

$$
\begin{equation*}
\lambda_{2}^{1 / 2}\left(\beta_{2 *}-\beta_{0}\right)=\mp \lambda^{1 / 2}\left(\beta_{*}-\beta_{0}\right) \tag{19.6}
\end{equation*}
$$

Substituting this into 19.5 yields

$$
\begin{align*}
& \quad \lambda_{2}^{1 / 2} d_{\beta_{2 *}}= \pm \lambda^{1 / 2} d_{\beta_{*}} \\
& \text { iff } \lambda_{2}^{1 / 2} d_{\beta_{0}}= \pm \lambda^{1 / 2}\left(d_{\beta_{0}}+2 r_{\beta_{0}}\left(\beta_{*}-\beta_{0}\right)\right) \\
& \text { iff } \lambda_{2}^{1 / 2}= \pm \lambda^{1 / 2} \frac{d_{\beta_{0}}+2 r_{\beta_{0}}\left(\beta_{*}-\beta_{0}\right)}{d_{\beta_{0}}} . \tag{19.7}
\end{align*}
$$

The square of the equation in the last line in 19.7) is the equation for $\lambda_{2}$ in 14.2.
Next, we show that (14.4) implies the equation for $\beta_{2 *}$ in (14.2). Using (19.6), the first equation in (14.4) can be written as

$$
\begin{equation*}
\beta_{2 *}=\beta_{0} \mp \frac{\lambda^{1 / 2}}{\lambda_{2}^{1 / 2}}\left(\beta_{*}-\beta_{0}\right) . \tag{19.8}
\end{equation*}
$$

This combined with the equation for $\lambda^{1 / 2} / \lambda_{2}^{1 / 2}$ obtained from the last line of 19.7 gives

$$
\begin{equation*}
\beta_{2 *}=\beta_{0}-\frac{d_{\beta_{0}}}{d_{\beta_{0}}+2 r_{\beta_{0}}\left(\beta_{*}-\beta_{0}\right)}\left(\beta_{*}-\beta_{0}\right) \tag{19.9}
\end{equation*}
$$

where a minus sign appears because the $\mp \operatorname{sign}$ in (19.8) gets multiplied by the $\pm$ sign in the last line of 19.7), which yields a minus sign in both cases. Equation 19.9) is the same as the first condition in 14.2. This completes the proof that (14.4) implies (14.2).

Now, we prove the converse. We suppose 14.2 holds. Taking the square root of the second equation in 14.2) gives

$$
\begin{equation*}
\lambda_{2}^{1 / 2}= \pm \lambda^{1 / 2} \frac{d_{\beta_{0}}+2 r_{\beta_{0}}\left(\beta_{*}-\beta_{0}\right)}{d_{\beta_{0}}} \tag{19.10}
\end{equation*}
$$

where the $\pm$ sign means that this equation holds either with + or with - . Substituting this into the first equation in $(14.2)$ gives $(19.8)$, which is the same as $\sqrt{19.6})$, and $\sqrt{19.6}$ ) is the first equation in (14.4).

The second equation in (14.4) is given by (19.5). Given that the first equation in (14.4) holds, the second equation in (14.4) is given in (19.7). The last line of 19.7) holds by 19.10. This completes the proof that (14.2) implies (14.4).

Proof of Lemma 14.2. The proof of part (a) of the lemma is essentially the same as that of Theorem 8(b) in AMS. The only change is to note that when $\left(\beta_{2 *}, \lambda_{2}\right)$ satisfies (14.3), we have $\tau^{*}=\tau_{2}^{*}, \delta^{*}=-\delta_{2}^{*}$, and $\delta_{\max }=\left|\delta^{*}\right|=\left|\delta_{2}^{*}\right|$ (using the notation in AMS). Because $\delta_{\max }=\left|\delta^{*}\right|=\left|\delta_{2}^{*}\right|$, we obtain $\sqrt{\delta^{2}}-\sqrt{\delta_{\max }^{2}}=0$ and the remainder of the proof of Theorem $8(\mathrm{~b})$ goes through as is.

The proof of part (b) of the lemma is quite similar to the proof of Theorem 8(c) of AMS. The latter proof first considers the case where " $\left(\beta_{2 *}, \lambda_{2}\right)$ does not satisfy the second condition of (14.1)." This needs to be changed to " $\left(\beta_{2 *}, \lambda_{2}\right)$ does not satisfy the second condition of (14.1) or 14.3)." With this change, the rest of that part of the proof of Theorem 8(c) goes through unchanged.

The remaining cases (where both (14.1) and 14.3) fail) to consider are (i) when the second condition in (14.1) holds and the first condition in (14.1) fails and (ii) when the second condition in (14.3) holds and the first condition in (14.3) fails. These are mutually exclusive scenarios because the second conditions in (14.1) and 14.3) are incompatible. The proof of Theorem 8(c) of AMS considers case (i) and proves the result of Theorem 8(c) for that case. The proof of Theorem 8(c) for case (ii) is quite similar to that for case (i) using (A.21) in AMS because $\delta^{*}=-\delta_{2}^{*}, \delta_{\max }=$ $\left|\delta^{*}\right|=\left|\delta_{2}^{*}\right|>0$, and $\tau^{*} \neq \tau_{2}^{*}$ imply that $\operatorname{sgn}\left(\delta^{*}\right)=-\operatorname{sgn}\left(\delta_{2}^{*}\right)$ and $\tau^{*} \operatorname{sgn}\left(\delta^{*}\right) \neq-\tau_{2}^{*} \operatorname{sgn}\left(\delta_{2}^{*}\right)$. This last inequality shows that the expression in (A.21) in AMS is a continuous function of $Q_{S T} Q_{T}^{-1 / 2}$ that is not even. (Note that (A.21) in AMS has a typo: the quantity $\tau_{2}^{*} \operatorname{sgn}\left(\delta^{*}\right)$ in its second summand
should be $\left.\tau_{2}^{*} \operatorname{sgn}\left(\delta_{2}^{*}\right).\right)$

## 20 Structural Error Variance Matrices under Distant Alternatives and Distant Null Hypotheses

Here, we compute the structural error variance matrices in scenarios 1 and 2 considered in (4.2) and (4.3) in Section 4. By design, the reduced-form variance matrix $\Omega$ is the same for $\beta_{0}$ and $\beta_{*}$ and, hence, does not vary between these two scenarios.

In scenario 1 in (4.2), the structural error variance matrix under $H_{0}$ is $\Sigma\left(\beta_{0}, \Omega\right)$, defined in (12.9). Under $H_{1}: \beta=\beta_{*}$, as $\left|\beta_{*}\right| \rightarrow \infty$, we have

$$
\begin{align*}
& \lim _{\beta_{*} \rightarrow \pm \infty} \rho_{u v}\left(\beta_{*}, \Omega\right)=\lim _{\beta_{*} \rightarrow \pm \infty} \frac{\omega_{12}-\omega_{2}^{2} \beta_{*}}{\left(\omega_{1}^{2}-2 \omega_{12} \beta_{*}+\omega_{2}^{2} \beta_{*}^{2}\right)^{1 / 2} \omega_{2}}=\mp 1 \text { and } \\
& \lim _{\left|\beta_{*}\right| \rightarrow \infty} \sigma_{u}^{2}\left(\beta_{*}, \Omega\right) / \sigma_{v}^{2}\left(\beta_{*}, \Omega\right)=\frac{\omega_{1}^{2}-2 \omega_{12} \beta_{*}+\omega_{2}^{2} \beta_{*}^{2}}{\omega_{2}^{2}}=\infty \tag{20.1}
\end{align*}
$$

where $\rho_{u v}\left(\beta_{*}, \Omega\right), \sigma_{u}^{2}\left(\beta_{*}, \Omega\right)$, and $\sigma_{v}^{2}\left(\beta_{*}, \Omega\right)$ are defined just below 12.9). Equation 20.1 shows that, for standard power envelope calculations, when the alternative hypothesis value $\beta_{*}$ is large in absolute value the structural variance matrix under $H_{1}$ exhibits correlation close to one in absolute value and a large ratio of structural to reduced-form variances.

In scenario 2 in 4.3), the structural error variance error matrix under $H_{*}$ is $\Sigma\left(\beta_{*}, \Omega\right)$. Under $H_{0}: \beta=\beta_{0}$, by exactly the same argument as in 20.1) with $\beta_{0}$ in place of $\beta_{*}$, we obtain

$$
\begin{equation*}
\lim _{\beta_{0} \rightarrow \pm \infty} \rho_{u v}\left(\beta_{0}, \Omega\right)=\mp 1 \text { and } \lim _{\left|\beta_{0}\right| \rightarrow \infty} \sigma_{u}^{2}\left(\beta_{0}, \Omega\right) / \sigma_{v}^{2}\left(\beta_{0}, \Omega\right)=\infty \tag{20.2}
\end{equation*}
$$

So, in scenario 2, when the null hypothesis value $\beta_{0}$ is large in absolute value the structural variance matrix under $H_{0}$ exhibits correlation close to one in absolute value and a large ratio of structural to reduced-form variances.

From a testing perspective, it is natural and time honored to fix the null hypothesis value $\beta_{0}$ and consider power as the alternative hypothesis value $\beta_{*}$ varies. On the other hand, a confidence set is the set of null hypothesis values $\beta_{0}$ for which one does not reject $H_{0}: \beta=\beta_{0}$. Hence, for a given true value $\beta_{*}$, the false coverage probabilities of the confidence set equal one minus its power as one varies $H_{0}: \beta=\beta_{0}$. Thus, from the confidence set perspective, it is natural to fix $\beta_{*}$ and consider power as $\beta_{0}$ varies.

## 21 Transformation of the $\boldsymbol{\beta}_{0}$ Versus $\boldsymbol{\beta}_{*}$ Testing Problem to a 0 Versus $\overline{\boldsymbol{\beta}}_{*}$ Testing Problem

In this section, we transform the general testing problem of $H_{0}: \beta=\beta_{0}$ versus $H_{1}: \beta=\beta_{*}$ for $\pi \in R^{k}$ and fixed $\Omega$ to a testing problem of $H_{0}: \bar{\beta}=0$ versus $H_{1}: \bar{\beta}=\bar{\beta}_{*}$ for some $\bar{\pi} \in R^{k}$ and some fixed $\bar{\Omega}$ whose diagonal elements equal one. This is done using the transformations given footnotes 7 and 8 of AMS, which argue that there is no loss in generality in the AMS numerical results to take $\omega_{1}^{2}=\omega_{2}^{2}=1$ and $\beta_{0}=0$. These results help link the numerical work done in this paper with that done in AMS.

Starting with the model in (2.1), we transform the model based on $\left(y_{1}, y_{2}\right)$ with parameters $(\beta, \pi)$ and fixed reduced-form variance matrix $\Omega$ to a model based on ( $\widetilde{y}_{1}, y_{2}$ ) with parameters $(\widetilde{\beta}, \pi)$ and fixed reduced-form variance matrix $\widetilde{\Omega}$, where

$$
\begin{align*}
\widetilde{y}_{1} & :=y_{1}-y_{2} \beta_{0}, \\
\widetilde{\beta} & :=\beta-\beta_{0}, \text { and } \\
\widetilde{\Omega} & :=\operatorname{Var}\left(\binom{\widetilde{y}_{1}}{y_{2}}\right)=\operatorname{Var}\left(\left[\begin{array}{cc}
1 & -\beta_{0} \\
0 & 1
\end{array}\right]\binom{y_{1}}{y_{2}}\right) \\
& =\left[\begin{array}{cc}
\omega_{1}^{2}-2 \omega_{12} \beta_{0}+\omega_{2}^{2} \beta_{0}^{2} & \omega_{12}-\omega_{2}^{2} \beta_{0} \\
\omega_{12}-\omega_{2}^{2} \beta_{0} & \omega_{2}^{2}
\end{array}\right] . \tag{21.1}
\end{align*}
$$

The transformed testing problem is $H_{0}: \widetilde{\beta}=0$ versus $H_{1}: \widetilde{\beta}=\widetilde{\beta}_{*}$, where $\widetilde{\beta}_{*}=\beta_{*}-\beta_{0}$, with parameter $\pi$ and reduced-form variance matrix $\widetilde{\Omega}$.

The matrix $\widetilde{\Omega}$ does not have diagonal elements equal to one, so we transform the model based on ( $\widetilde{y}_{1}, y_{2}$ ) with parameters ( $\left.\widetilde{\beta}, \pi\right)$ and fixed reduced-form variance matrix $\widetilde{\Omega}$ to a model based on $\left(\bar{y}_{1}, \bar{y}_{2}\right)$ with parameters $(\bar{\beta}, \bar{\pi})$ and fixed reduced-form variance matrix $\bar{\Omega}$, wher ${ }^{144}$

$$
\begin{align*}
\bar{y}_{1} & :=\frac{\widetilde{y}_{1}}{\widetilde{\omega}_{1}}=\frac{y_{1}-y_{2} \beta_{0}}{\left(\omega_{1}^{2}-2 \omega_{12} \beta_{0}+\omega_{2}^{2} \beta_{0}^{2}\right)^{1 / 2}} \\
\bar{y}_{2} & :=\frac{1}{\widetilde{\omega}_{2}} y_{2}=\frac{1}{\omega_{2}} y_{2}, \\
\bar{\beta} & :=\frac{\widetilde{\omega}_{2} \widetilde{\widetilde{\omega}_{1}} \widetilde{\beta}=\frac{\omega_{2}}{\left(\omega_{1}^{2}-2 \omega_{12} \beta_{0}+\omega_{2}^{2} \beta_{0}^{2}\right)^{1 / 2}}\left(\beta-\beta_{0}\right), \text { and }}{\bar{\pi}}:=\frac{1}{\widetilde{\omega}_{2}} \pi=\frac{1}{\omega_{2}} \pi .
\end{align*}
$$

[^12]In addition, we have

$$
\begin{align*}
\bar{\Omega} & :=\operatorname{Var}\binom{\bar{y}_{1}}{\bar{y}_{2}}=\operatorname{Var}\left(\left[\begin{array}{cc}
1 / \widetilde{\omega}_{1} & 0 \\
0 & 1 / \widetilde{\omega}_{2}
\end{array}\right]\binom{\widetilde{y}_{1}}{y_{2}}\right) \\
& =\left[\begin{array}{cc}
1 / \widetilde{\omega}_{1} & 0 \\
0 & 1 / \widetilde{\omega}_{2}
\end{array}\right] \widetilde{\Omega}\left[\begin{array}{cc}
1 / \widetilde{\omega}_{1} & 0 \\
0 & 1 / \widetilde{\omega}_{2}
\end{array}\right] \\
& =\left[\begin{array}{cc}
1 / \widetilde{\omega}_{1} & 0 \\
0 & 1 / \omega_{2}
\end{array}\right]\left[\begin{array}{cc}
\omega_{1}^{2}-2 \omega_{12} \beta_{0}+\omega_{2}^{2} \beta_{0}^{2} & \omega_{12}-\omega_{2}^{2} \beta_{0} \\
\omega_{12}-\omega_{2}^{2} \beta_{0} & \omega_{2}^{2}
\end{array}\right]\left[\begin{array}{cc}
1 / \widetilde{\omega}_{1} & 0 \\
0 & 1 / \omega_{2}
\end{array}\right] \\
& =\left[\begin{array}{cc}
1 & \frac{\omega_{12}-\omega_{2}^{2} \beta_{0}}{\left(\omega_{1}^{2}-2 \omega_{12} \beta_{0}+\omega_{2}^{2} \beta_{0}^{2}\right)^{1 / 2} \omega_{2}} \\
\frac{\omega_{12}-\omega_{2}^{2} \beta_{0}}{\left(\omega_{1}^{2}-2 \omega_{12} \beta_{0}+\omega_{2}^{2} \beta_{0}^{2}\right)^{1 / 2} \omega_{2}} & 1
\end{array}\right] . \tag{21.3}
\end{align*}
$$

The transformed testing problem is $H_{0}: \bar{\beta}=0$ versus $H_{1}: \bar{\beta}=\bar{\beta}_{*}$, where

$$
\begin{equation*}
\bar{\beta}_{*}=\frac{\omega_{2}}{\left(\omega_{1}^{2}-2 \omega_{12} \beta_{0}+\omega_{2}^{2} \beta_{0}^{2}\right)^{1 / 2}}\left(\beta_{*}-\beta_{0}\right), \tag{21.4}
\end{equation*}
$$

with parameter $\bar{\pi}$ and reduced-form variance matrix $\bar{\Omega}$.
Now, we consider the limit as $\beta_{0} \rightarrow \pm \infty$ of the original model and see what it yields in terms of the transformed model. We have

$$
\lim _{\beta_{0} \rightarrow \pm \infty} \bar{\beta}_{*}=\mp 1 \text { and } \lim _{\beta_{0} \rightarrow \pm \infty} \bar{\Omega}=\left[\begin{array}{cc}
1 & \mp 1  \tag{21.5}\\
\mp 1 & 1
\end{array}\right] .
$$

So, the asymptotic testing problem as $\beta_{0} \rightarrow \pm \infty$ in terms of a model with a null hypothesis $\bar{\beta}$ value of 0 and a reduced-form variance matrix $\bar{\Omega}$ with ones on the diagonal is a test of $H_{0}: \bar{\beta}=0$ versus $H_{1}: \bar{\beta}=\mp 1$.

We get the same expression for the limits as $\beta_{0} \rightarrow \pm \infty$ of $c_{\beta_{*}}\left(\beta_{0}, \Omega\right)$ and $d_{\beta_{*}}\left(\beta_{0}, \Omega\right)$ written in terms of the transformed parameters $\left(\bar{\beta}_{0}, \bar{\beta}_{*}, \bar{\pi}, \bar{\Omega}\right)$ as in Lemma 15.1 except they are multiplied by $\sigma_{v}$. This occurs because $\mu_{\bar{\pi}}=\mu_{\pi} / \sigma_{v}$. In consequence, the limits as $\beta_{0} \rightarrow \pm \infty$ of $c_{\beta_{*}}\left(\beta_{0}, \Omega\right) \mu_{\pi}$ and $d_{\beta_{*}}\left(\beta_{0}, \Omega\right) \mu_{\pi}$ written in terms of the transformed parameters $\left(\bar{\beta}_{0}, \bar{\beta}_{*}, \bar{\pi}, \bar{\Omega}\right)$ are the same as their limits without any transformation.

Lemma 21.1 Let $\bar{\beta}_{*}=\bar{\beta}_{*}\left(\beta_{0}\right)$ and $\bar{\Omega}=\bar{\Omega}\left(\beta_{0}\right)$ be defined in 21.4 and 21.3), respectively. Let $\bar{\beta}_{0}\left(\beta_{0}\right)=0$.
(a) $\lim _{\beta_{0} \rightarrow \pm \infty} c_{\bar{\beta}_{*}\left(\beta_{0}\right)}\left(\bar{\beta}_{0}\left(\beta_{0}\right), \bar{\Omega}\left(\beta_{0}\right)\right)=\mp 1$.
(b) $\lim _{\beta_{0} \rightarrow \pm \infty} d_{\bar{\beta}_{*}\left(\beta_{0}\right)}\left(\bar{\beta}_{0}\left(\beta_{0}\right), \bar{\Omega}\left(\beta_{0}\right)\right)=\mp \frac{\rho_{u v}}{\left(1-\rho_{u v}\right)^{1 / 2}}$.

Comment. (i). By Lemmas 15.1 and 21.1 , the distributions of all of the tests considered in this paper are the same in the model in Section 2 when $\beta_{*}$ and $\Omega$ are fixed and the null hypothesis value $\beta_{0}$ satisfies $\beta_{0} \rightarrow \pm \infty$, and in the transformed model of this section when the null hypothesis $\bar{\beta}_{0}$ is fixed at 0 and the alternative hypothesis value $\bar{\beta}_{*}=\bar{\beta}_{*}\left(\beta_{0}\right)$ and the reduced-form variance $\bar{\Omega}=\bar{\Omega}\left(\beta_{0}\right)$ converge as in 21.5) as $\beta_{0} \rightarrow \pm \infty$. (This uses the fact that $\sigma_{v}=1$ in Lemma 21.1.)
(ii). AMS footnote 5 notes that there is a special parameter value $\beta=\beta_{A R}$ at which the onesided point optimal invariant similar test of $H_{0}: \beta=\beta_{0}$ versus $H_{1}: \beta=\beta_{A R}$ is the (two-sided) AR test. In footnote $5 \beta_{A R}$ is defined to be $\beta_{A R}=\frac{\omega_{1}^{2}-\omega_{12} \beta_{0}}{\omega_{12}-\omega_{2}^{2} \beta_{0}}$. If we compute $\beta_{A R}$ for the transformed model $\left(\bar{y}_{1}, \bar{y}_{2}\right)$ with parameters $(\bar{\beta}, \bar{\pi}, \bar{\Omega})$, where $\bar{\beta}_{0}=0$, we obtain

$$
\begin{equation*}
\bar{\beta}_{A R}=\frac{\bar{\omega}_{1}^{2}-\bar{\omega}_{12} \bar{\beta}_{0}}{\bar{\omega}_{12}-\bar{\omega}_{2}^{2} \bar{\beta}_{0}}=\frac{1}{\bar{\omega}_{12}}=\mp 1, \tag{21.6}
\end{equation*}
$$

which is the same as the limit of $\bar{\beta}_{*}=\bar{\beta}_{*}\left(\beta_{0}\right)$ as $\beta_{0} \rightarrow \pm \infty$ in 21.2.

Proof of Lemma 21.1. First, we prove part (a). We have

$$
\begin{align*}
c_{\bar{\beta}_{*}}\left(\bar{\beta}_{0}, \bar{\Omega}\right) & =\left(\bar{\beta}_{*}-\bar{\beta}_{0}\right)\left(\bar{b}_{0}^{\prime} \bar{\Omega} \bar{b}_{0}\right)^{-1 / 2} \\
& =\frac{\omega_{2}}{\left(\omega_{1}^{2}-2 \omega_{12} \beta_{0}+\omega_{2}^{2} \beta_{0}^{2}\right)^{1 / 2}}\left(\beta_{*}-\beta_{0}\right)\left(1-2 \bar{\omega}_{12} \bar{\beta}_{0}+\bar{\beta}_{0}^{2}\right)^{-1 / 2} \\
& =\frac{\omega_{2}\left(\beta_{*}-\beta_{0}\right)}{\left(\omega_{1}^{2}-2 \omega_{12} \beta_{0}+\omega_{2}^{2} \beta_{0}^{2}\right)^{1 / 2}} \\
& \rightarrow \mp 1 \text { as } \beta_{0} \rightarrow \pm \infty, \tag{21.7}
\end{align*}
$$

where the second equality uses 21.4 and the third equality uses $\bar{\beta}_{0}=0$. Hence, $c_{\bar{\beta}_{*}}\left(\bar{\beta}_{0}, \bar{\Omega}\right) \mu_{\bar{\pi}} \rightarrow$ $\mp\left(1 / \sigma_{v}\right) \mu_{\pi}$ as $\beta_{0} \rightarrow \pm \infty$ using the expression for $\bar{\pi}$ in 21.2) and $\omega_{2}=\sigma_{v}$.

Next, we prove part (b). Let $\bar{b}_{*}=\left(1,-\bar{\beta}_{*}\right)^{\prime}$ and $\bar{b}_{0}=\left(1,-\bar{\beta}_{0}\right)^{\prime}$. We have

$$
\begin{align*}
\operatorname{det}(\bar{\Omega}) & =1-\bar{\omega}_{12}^{2}, \\
\bar{\omega}_{12} & =\frac{\omega_{12}-\omega_{2}^{2} \beta_{0}}{\left(\omega_{1}^{2}-2 \omega_{12} \beta_{0}+\omega_{2}^{2} \beta_{0}^{2}\right)^{1 / 2} \omega_{2}}, \text { and } \\
\bar{b}_{*}^{\prime} \bar{\Omega}_{0}\left(\bar{b}_{0}^{\prime} \bar{\Omega}_{0}\right)^{-1 / 2} & =\frac{1-\bar{\omega}_{12} \bar{\beta}_{0}-\bar{\omega}_{12} \bar{\beta}_{*}+\bar{\beta}_{0} \bar{\beta}_{*}}{\left(1-2 \bar{\omega}_{12} \bar{\beta}_{0}+\bar{\beta}_{0}^{2}\right)^{1 / 2}}=1-\bar{\omega}_{12} \bar{\beta}_{*}, \tag{21.8}
\end{align*}
$$

where the second equality on the third line uses $\bar{\beta}_{0}=0$. Next, we have

$$
\begin{align*}
1-\bar{\omega}_{12} \bar{\beta}_{*} & =1-\frac{\omega_{12}-\omega_{2}^{2} \beta_{0}}{\left(\omega_{1}^{2}-2 \omega_{12} \beta_{0}+\omega_{2}^{2} \beta_{0}^{2}\right)^{1 / 2} \omega_{2}} \frac{\omega_{2}}{\left(\omega_{1}^{2}-2 \omega_{12} \beta_{0}+\omega_{2}^{2} \beta_{0}^{2}\right)^{1 / 2}}\left(\beta_{*}-\beta_{0}\right) \\
& =1-\frac{\left(\omega_{12}-\omega_{2}^{2} \beta_{0}\right)\left(\beta_{*}-\beta_{0}\right)}{\omega_{1}^{2}-2 \omega_{12} \beta_{0}+\omega_{2}^{2} \beta_{0}^{2}} \\
& =\frac{\omega_{1}^{2}-2 \omega_{12} \beta_{0}+\omega_{2}^{2} \beta_{0}^{2}-\omega_{12} \beta_{*}+\omega_{12} \beta_{0}+\omega_{2}^{2} \beta_{0} \beta_{*}-\omega_{2}^{2} \beta_{0}^{2}}{\omega_{1}^{2}-2 \omega_{12} \beta_{0}+\omega_{2}^{2} \beta_{0}^{2}} \\
& =\frac{\omega_{1}^{2}-\omega_{12} \beta_{0}-\omega_{12} \beta_{*}+\omega_{2}^{2} \beta_{0} \beta_{*}}{\omega_{1}^{2}-2 \omega_{12} \beta_{0}+\omega_{2}^{2} \beta_{0}^{2}}, \tag{21.9}
\end{align*}
$$

where the first equality uses (21.3) and (21.4).
In addition, we have

$$
\begin{align*}
1-\bar{\omega}_{12}^{2} & =1-\frac{\left(\omega_{12}-\omega_{2}^{2} \beta_{0}\right)^{2}}{\left(\omega_{1}^{2}-2 \omega_{12} \beta_{0}+\omega_{2}^{2} \beta_{0}^{2}\right) \omega_{2}^{2}} \\
& =\frac{\omega_{1}^{2} \omega_{2}^{2}-2 \omega_{12} \omega_{2}^{2} \beta_{0}+\omega_{2}^{4} \beta_{0}^{2}-\omega_{12}^{2}+2 \omega_{12} \omega_{2}^{2} \beta_{0}-\omega^{4} \beta_{0}^{2}}{\left(\omega_{1}^{2}-2 \omega_{12} \beta_{0}+\omega_{2}^{2} \beta_{0}^{2}\right) \omega_{2}^{2}} \\
& =\frac{\omega_{1}^{2} \omega_{2}^{2}-\omega_{12}^{2}}{\left(\omega_{1}^{2}-2 \omega_{12} \beta_{0}+\omega_{2}^{2} \beta_{0}^{2}\right) \omega_{2}^{2}}, \tag{21.10}
\end{align*}
$$

where the first equality uses 21.8 .
Using (21.8)-21.10), we have

$$
\begin{align*}
d_{\bar{\beta}_{*}}\left(\bar{\beta}_{0}, \bar{\Omega}\right) & =\bar{b}_{*}^{\prime}{\bar{\Omega} b_{0}}\left(\bar{b}_{0}^{\prime} \bar{\Omega}_{0}\right)^{-1 / 2} \operatorname{det}(\bar{\Omega})^{-1 / 2} \\
& =\frac{\omega_{1}^{2}-\omega_{12} \beta_{0}-\omega_{12} \beta_{*}+\omega_{2}^{2} \beta_{0} \beta_{*}}{\omega_{1}^{2}-2 \omega_{12} \beta_{0}+\omega_{2}^{2} \beta_{0}^{2}}\left(\frac{\omega_{1}^{2} \omega_{2}^{2}-\omega_{12}^{2}}{\left(\omega_{1}^{2}-2 \omega_{12} \beta_{0}+\omega_{2}^{2} \beta_{0}^{2}\right) \omega_{2}^{2}}\right)^{-1 / 2} \\
& =\frac{\left(\omega_{1}^{2}-\omega_{12} \beta_{0}-\omega_{12} \beta_{*}+\omega_{2}^{2} \beta_{0} \beta_{*}\right)}{\left(\omega_{1}^{2}-2 \omega_{12} \beta_{0}+\omega_{2}^{2} \beta_{0}^{2}\right)^{1 / 2}\left(\omega_{1}^{2} \omega_{2}^{2}-\omega_{12}^{2}\right)^{1 / 2}} \omega_{2} . \tag{21.11}
\end{align*}
$$

The rhs of (21.11) is the same as the expression on the second line of 15.2 multiplied by $\omega_{2}=\sigma_{v}$. In consequence, the calculations in $(15.2$ - $(15.4)$ give the result of part (a) of Lemma 21.1 ,

## 22 Transformation of the $\boldsymbol{\beta}_{0}$ Versus $\boldsymbol{\beta}_{*}$ Testing Problem to a $\overline{\boldsymbol{\beta}}_{0}$ Versus 0 Testing Problem

In this section, we transform the general testing problem of $H_{0}: \beta=\beta_{0}$ versus $H_{1}: \beta=\beta_{*}$ for $\pi \in R^{k}$ and fixed reduced-form variance matrix $\Omega$ to a testing problem of $H_{0}: \bar{\beta}=\bar{\beta}_{0}$ versus $H_{1}: \bar{\beta}=0$ for some $\bar{\pi} \in R^{k}$ and some fixed $\bar{\Omega}$ with diagonal elements equal to one. These
transformation results imply that there is no loss in generality in the numerical results of the paper to taking $\omega_{1}^{2}=\omega_{2}^{2}=1$ and $\beta_{*}=0$. We also show that there is no loss in generality in the numerical results of the paper to taking $\rho_{u v} \in[0,1]$, rather than $\rho_{u v} \in[-1,1]$, where $\rho_{u v}$ is the structural variance matrix correlation defined in (5.5).

We consider the same transformations as in Section 21, but with $\beta_{*}$ in place of $\beta_{0}$ in (21.1)-(21.3) and with the roles of $\beta_{*}$ and $\beta_{0}$ reversed in (21.4) and (21.5). The transformed testing problem given the transformations in (with $\beta_{*}$ in place of $\beta_{0}$ ) is $H_{0}: \widetilde{\beta}=\widetilde{\beta}_{0}$ versus $H_{1}: \widetilde{\beta}=0$, where $\widetilde{\beta}_{0}=\beta_{0}-\beta_{*}$, with parameter $\pi$ and reduced-form variance matrix $\widetilde{\Omega}$. The transformed testing problem given the transformations in 21.1)-21.3 (with $\beta_{*}$ in place of $\beta_{0}$ ) is $H_{0}: \bar{\beta}=\bar{\beta}_{0}$ versus $H_{1}: \bar{\beta}=0$, where $\widetilde{\beta}_{0}=\beta_{0}-\beta_{*}$, with parameters $\bar{\beta}, \bar{\pi}$, and $\bar{\Omega}$ defined in 21.2) and 21.3) (with the roles of $\beta_{*}$ and $\beta_{0}$ reversed).

For example, a scenario in which a typical test has high power in the original scenario of testing $H_{0}: \beta=\beta_{0}$ versus $H_{1}: \beta=\beta_{*}$, such as $\beta_{0}=0$ and $\left|\beta_{*}\right|$ large, gets transformed into the testing problem of $H_{0}: \bar{\beta}=\bar{\beta}_{0}$ versus $H_{1}: \bar{\beta}=0$ with correlation $\bar{\omega}_{12}$ (the (1,2) element of $\bar{\Omega}$ ) close to $\pm 1$, because by 21.5 (with the roles of $\beta_{*}$ and $\beta_{0}$ reversed) we have

$$
\lim _{\beta_{*} \rightarrow \pm \infty} \bar{\Omega}=\left[\begin{array}{cc}
1 & \mp 1  \tag{22.1}\\
\mp 1 & 1
\end{array}\right] .
$$

In this case, we also have $\lim _{\beta_{*} \rightarrow \pm \infty} \bar{\beta}_{0}=\mp 1$ by 21.5). Also, note that the reduced-form and structural variances matrices are equal when the alternative hypothesis holds in the testing problem $H_{0}: \bar{\beta}=\bar{\beta}_{0}$ versus $H_{1}: \bar{\beta}=0$, so the result in 22.1) also applies to the structural variance matrix $\Sigma(\bar{\beta}, \bar{\Omega})$ when $\bar{\beta}=0$ whose correlation we denote by $\bar{\rho}_{u v}$, i.e., $\lim _{\beta_{*} \rightarrow \pm \infty} \bar{\rho}_{u v}=\mp 1$. Here the parameter $\bar{\rho}_{u v}$ is the parameter $\rho_{u v}$ that appears in the tables in the paper. These results are useful in showing how the numerical results of the paper apply to general hypotheses of the form $H_{0}: \beta=\beta_{0}$ versus $H_{1}: \beta=\beta_{*}$.

Next, we show that there is no loss in generality in the numerical results of the paper to taking $\rho_{u v} \in[0,1]$. We consider the hypotheses $H_{0}: \beta=\beta_{0}$ versus $H_{1}: \beta=0$, as in the numerical results in the paper. When the true $\beta$ equals 0 and $\Omega$ has ones on its diagonal, the reduced-form and structural variance matrices are equal, see $\sqrt{12.9}$ ). Hence, the correlation $\omega_{12}$ given by $\Omega$ equals the structural variance correlation $\rho_{u v}$ in power calculations in the paper, and it suffices to show that there is no loss in generality in the numerical results of the paper to taking $\omega_{12} \in[0,1]$.

By 2.3), the distributions of $S$ and $T$ only depend on $c_{\beta}\left(\beta_{0}, \Omega\right), d_{\beta}\left(\beta_{0}, \Omega\right)$, and $\mu_{\pi}:=\left(Z^{\prime} Z\right)^{1 / 2} \pi$. The vector $\mu_{\pi}$ does not depend on $\beta$, $\beta_{0}$, or $\Omega$. First, note that $\omega_{12}$ enters $c_{\beta}\left(\beta_{0}, \Omega\right):=(\beta-$ $\left.\beta_{0}\right)\left(b_{0}^{\prime} \Omega b_{0}\right)^{-1 / 2}=\left(\beta-\beta_{0}\right)\left(\omega_{1}^{2}-2 \omega_{12} \beta_{0}+\omega_{2}^{2} \beta_{0}^{2}\right)^{-1 / 2}$ only through $\omega_{12} \beta_{0}$. In consequence, the
distribution of $S$ is the same under $\left(\beta_{0}, \omega_{12}\right)$ as under $\left(-\beta_{0},-\omega_{12}\right)$. Second, by (2.8) of AMS, $d_{\beta}\left(\beta_{0}, \Omega\right)$ can be written as $b^{\prime} \Omega b_{0}\left(b_{0}^{\prime} \Omega b_{0}\right)^{-1 / 2} \operatorname{det}(\Omega)^{-1 / 2}$, where $b:=(1,-\beta)^{\prime}$. The distribution of $T$ when $\beta=0$ depends on $d_{0}\left(\beta_{0}, \Omega\right)=\left(1-\omega_{12} \beta_{0}\right)\left(b_{0}^{\prime} \Omega b_{0}\right)^{-1 / 2} \operatorname{det}(\Omega)^{-1 / 2}$. The first two multiplicands depend on $\omega_{12}$ only through $\omega_{12} \beta_{0}$ and the third multiplicand only depends on $\omega_{12}$ through $\omega_{12}^{2}$ (because $\operatorname{det}(\Omega)=1-\omega_{12}^{2}$ ). In addition, $S$ and $T$ are independent. Hence, the distribution of [ $S: T$ ] for given $\left(\beta_{0}, \omega_{12}\right)$ when $\beta=0$ equals its distribution under $\left(-\beta_{0},-\omega_{12}\right)$ when $\beta=0$. Thus, the power of a test of $H_{0}: \beta=\beta_{0}$ versus $H_{1}: \beta=0$ when $\omega_{12}<0$ equals its power for testing $H_{0}: \beta=-\beta_{0}$ versus $H_{1}: \beta=0$ for $-\omega_{12}>0$.

## 23 Additional Numerical Results

This section contains Tables SM-I,..., SM-V and Figure SM-I, which provide additional numerical results to those in Tables I,..., V in the main paper.

Table SM-I is analogous to Table I, but considers AR and POIS $\infty_{\infty}$ CS's, in addition to the CLR and POIS2 $\infty_{\infty}$ CS's. Here, POIS $_{\infty}$ denotes the CS obtained from the optimal one-sided invariant similar test as $\beta_{0} \rightarrow \pm \infty$ defined in 13.5 in Section 13.2. Table SM-I reports probabilities of infinite length, as well as differences in probabilities of infinite length (DPIL's) for CLR and AR, AR and POIS $2_{\infty}$, and CLR and POIS2 $\infty_{\infty}$ CS's. In addition, it reports simulation standard deviations for the first and third DPIL's.

The results for the DPIL's vary greatly with $\rho_{u v}$. When $\rho_{u v}=0$, the AR CS is the same as the optimal POIS $_{\infty}$ CS and the CLR-AR DPIL's range over [.001, .049] as $(k, \lambda)$ vary. On the other hand, when $\rho_{u v}=.9$, the AR CS is far from optimal and the CLR-AR DPIL's range over $[-.002,-.421]$ as $(k, \lambda)$ vary. In sum, when $\rho_{u v} \geq .5$, the AR CS can, and typically does, perform noticeably worse than the CLR CS in terms of DPIL's.

Table SM-II reports more detailed results than those given in Table II. Table SM-II reports the maximum power differences (PD's) over $\beta_{0}$ values between the POIS2 power envelope and the CLR test for a grid of $\left(k, \rho_{u v}, \lambda\right)$ values. (In contrast, Table II reports maximum and average PD's over $\left(\beta_{0}, \lambda\right)$ values for a grid of $\left(k, \rho_{u v}\right)$ values.) Table SM-II shows that the maximum (over $\beta_{0}$ ) PD's vary substantially over $\lambda$ values for $\rho_{u v} \leq .7$ values and less so for $\rho_{u v}=.9$. For example, for $k=5$ and $\rho_{u v}=.0, .3, .5, .7, .9$, the PD's ranges (over $\lambda$ values) are [.004, .030], [.008, .034], [.007, .029], [.005, .033], [.001, .017], respectively.

Tables SM-III and SM-IV are the same as Table II except they consider the AR and LM tests, respectively, rather than the CLR test. As noted in the main paper, Tables SM-III and SM-IV show that the power of the AR and LM tests is much farther from the POIS2 power envelope than
is the power of the CLR test. Table $\operatorname{SM-III(a)~shows~that~the~maximum~and~average~(over~(~} \beta_{0}, \lambda$ )) PD's for the AR test are increasing in $k$ up to $k=20$, but drop going from $k=20$ to 40 . (This drop may be due to the choice of $\lambda$ values considered. The choice yields the $\lambda_{\text {max }}$ value for the AR test to be on the upper bound of the values considered.) Table SM-III(b) shows that the maximum and average (over $\left(\beta_{0}, \lambda\right)$ ) PD's for the AR test are increasing in $\rho_{u v}$ for all values of $k$, which is the opposite of the pattern for the CLR test. Table SM-III(b) also shows that the $\lambda_{\max }$ values are at the boundary of the grid of $\lambda$ values considered for all $k$.

Table $\operatorname{SM}-\operatorname{IV}(\mathrm{a})$ shows that the maximum and average PD's (over $\left(\beta_{0}, \lambda\right)$ ) for the LM test are clearly increasing in $k$, except that for $\rho_{u v}=0, .3$ there is a drop from $k=20$ to 40 (which may be due to the choice of $\lambda$ values considered, as for the AR test). Table SM-IV(b) shows that the maximum and average (over $\left(\beta_{0}, \lambda\right)$ ) PD's for the LM test are decreasing in $\rho_{u v}$ for all values of $k$, as for the CLR test. Table $\operatorname{SM}-\mathrm{IV}(\mathrm{b})$ also shows that the $\lambda_{\max }$ values decrease in $\rho_{u v}$ for each $k$, as with the CLR test.

Table SM-V is the same as Table III except that it reports results for $k=2,5,10,20$, and 40, rather than just $k=5$. It also reports results for a finer grid of $\beta_{0}$ values than in Table IV and it reports the power of the WAP2 test, in addition to the difference in power between the WAP2 and CLR tests.

Figure SM-I provides graphs that are the same as in AMS, but with $\rho_{\Omega}=0$, rather than $\rho_{\Omega}=.5$ or .95. Specifically, these graphs provide the power of the significance level . 05 CLR, LM, and AR tests and the POIS2 power envelope for fixed null value $\beta_{0}=0$, varying true value $\beta^{*}, k=2,5,10$ and $\lambda=5,20$. The number of simulation repetitions used to construct the power functions is 5,000 and 100,000 repetitions are used to compute the null distribution of the POIS2 statistic to obtain its p-values.

Figure SM-I shows that the power of the CLR test is very close to the POIS2 power envelope in the scenarios considered. In fact, the maximum differences are $.0074, .0040, .0110, .0062, .0102$, and .0090 in the six graphs in Figure SM-I. Note that $\rho_{\Omega}=0$ is the $\rho_{\Omega}$ value that yields many of the largest differences between the power of the CLR test and the POIS2 power envelope when the true $\beta^{*}=0$ is fixed and the null value $\beta_{0}$ varies, as shown in Tables II and SM-II ${ }^{15}$ The results in Figure SM-I show that standard power graphs with $\beta_{0}=0$ fixed and true $\beta^{*}$ varying, as in AMS, do not pick up the relatively large differences between the power of the CLR test and the POIS2 power envelope that appear in some $\rho_{\Omega}=0$ parameter configurations considered in Tables II and SM-II.

[^13]
## 24 Unknown Variance CLR Test

In this section, we consider a different form of the CLR test to see whether it has smaller probabilities of infinite length than the CLR test defined in (3.3) and (3.4..$^{16}$ By Moreira (2003, pp. 1036, 1045), the likelihood ratio statistic under the assumption that the reduced-form variance matrix is unknown is

$$
\begin{align*}
L R_{U} & :=\frac{n}{2} \ln \left(1+\frac{b_{0}^{\prime} Y P_{Z} Y b_{0}}{(n-k) b_{0}^{\prime} \widehat{\Omega} b_{0}}\right)-\frac{n}{2} \ln \left(1+\frac{\lambda_{\min }\left(\widehat{\Omega}^{-1 / 2} Y P_{Z} Y \widehat{\Omega}^{-1 / 2}\right)}{n-k}\right), \text { where } \\
\widehat{\Omega} & :=Y M_{Z} Y /(n-k) . \tag{24.1}
\end{align*}
$$

(Note that Moreira (2003) denotes the statistic $L R_{U}$ by $L R$ and the statistic $L R$ in (3.3) above by $L R_{0}$.)

The probabilities that the CLR test has infinite length (given in Table I in Section 7) are computed under the assumption that $\Omega$ is known. If we made comparisons of these results to analogous results for the conditional test that employs the statistic $L R_{U}$ (combined with the same conditional critical value as in (3.4), the comparisons would be misleading because $L R_{U}$ does not make use of the known value of $\Omega$. To obtain a fair comparison, we alter the $L R_{U}$ statistic by replacing $\widehat{\Omega}$ by $\Omega$. The resulting statistic is

$$
\begin{align*}
L R 2_{n} & :=\frac{n}{2} \ln \left(1+\frac{b_{0}^{\prime} Y P_{Z} Y b_{0}}{(n-k) b_{0}^{\prime} \Omega b_{0}}\right)-\frac{n}{2} \ln \left(1+\frac{\lambda_{\min }\left(\Omega^{-1 / 2} Y P_{Z} Y \Omega^{-1 / 2}\right)}{n-k}\right) \\
& =\frac{n}{2} \ln \left(1+\frac{Q_{S}}{(n-k)}\right)-\frac{n}{2} \ln \left(1+\frac{Q_{S}-L R}{n-k}\right), \tag{24.2}
\end{align*}
$$

where the second equality holds by the definition of $Q_{S}$ in (2.3) and (3.1) and the expression $L R_{0}=$ $\bar{S}^{\prime} \bar{S}-\bar{\lambda}_{\min }$ on p. 1033 of Moreira (2003), which in the notation of this paper is $L R=Q_{S}-\bar{\lambda}_{\text {min }}$ for $\bar{\lambda}_{\text {min }}:=\lambda_{\text {min }}\left(\Omega^{-1 / 2} Y P_{Z} Y \Omega^{-1 / 2}\right)$ by p. 1045 of Moreira (2003).

The conditional critical value for this statistic is the same as that in (3.4). We call the resulting test the CLR $2_{n}$ test. Somewhat confusingly, or perhaps paradoxically, the form of the $L R 2_{n}$ statistic is determined by assuming $\Omega$ is unknown, which yields a test that depends on an estimator $\widehat{\Omega}$ of $\Omega$, which we then replace by $\Omega$, which yields a test for the case where $\Omega$ is known. Note that the $L R 2_{n}$ statistic depends on $n$, whereas the $L R$ statistic in (3.3) does not.

Table SM-VI reports differences in the probabilities that the CLR2 $2_{n}$ and CLR CI's have infinite length for the same $k, \lambda$, and $\rho_{u v}$ values as in Table I, for three values of $n$ : $n=100,500$, and 1,000 .

[^14]Note that the data generating process depends only on $k$, $\lambda$, and $\rho_{u v}$, and not on $n$. The quantity $n$ only enters through the form of the $L R 2_{n}$ statistic.

The results in Table SM-VI show that the CLR2 ${ }_{n}$ and CLR CI's perform very similarly. This is especially true for $n=500$ and 1,000 in which cases all differences are less than .005 . For $n=100$, the differences exceed .005 in some scenarios where $\rho_{u v}$ is small $(0, .3$, and .5$)$ and $k$ is large $(k \geq 10$ for $\rho_{u v}=.0, .3$ and $k \geq 20$ for $\left.\rho_{u v}=.5\right)$. The largest difference is .0235 and is achieved when $n=100, \rho_{u v}=0, k=40$, and $\lambda=20$.

Based on these results, we do not find that the CLR2 ${ }_{n}$ test improves on the CLR test in terms of its probabilities of having infinite length. The differences between the CLR $2_{n}$ and CLR tests are quite small, especially for $n=500$ and 1000 .

## 25 Heteroskedastic and Autocorrelated Model

Theorem 5.1 gives formulae for the probabilities that certain CI's have infinite right length, infinite left length, and infinite length in the homoskedastic Gaussian linear IV model. In this section, we extend these results to the Gaussian linear IV model that allows for heteroskedasticity and autocorrelation (HC) in the errors. We use the specification and notation in Moreira and Ridder (2017). The reduced-form model is $Y=Z \pi a^{\prime}+V$, as in (2.2), but without the assumption that the rows of $V$ are i.i.d. with distribution $\Omega$. Rather, we assume that

$$
\begin{equation*}
\operatorname{vec}(\widetilde{V}):=\operatorname{vec}\left(\left(Z^{\prime} Z\right)^{-1 / 2} Z^{\prime} V\right) \sim N(0, \Sigma), \tag{25.1}
\end{equation*}
$$

where $\widetilde{V} \in R^{k \times 2}$ and $\Sigma$ is a positive definite $2 k \times 2 k$ matrix. The matrix $\Sigma$ can be consistently estimated. In consequence, we focus on the case where $\Sigma$ is known. Let $P_{1}:=Z\left(Z^{\prime} Z\right)^{-1 / 2} \in R^{n \times k}$ and let $P_{2} \in R^{n \times(n-k)}$ be such that $P:=\left[P_{1}: P_{2}\right]$ is orthogonal. A one-to-one transformation of $Y$ is $\left(P_{1}^{\prime} Y, P_{2}^{\prime} Y\right)$. The matrix $P_{2}^{\prime} Y$ is ancillary and the variance of $V$ is only restricted by $\operatorname{Var}\left(\operatorname{vec}\left(P_{1}^{\prime} V\right)\right)=\Sigma$. In consequence, we only consider tests that are a function of $P_{1}^{\prime} Y$. We have

$$
\begin{equation*}
R:=P_{1}^{\prime} Y=\mu_{\pi} a^{\prime}+\tilde{V}, \text { where } \mu_{\pi}:=\left(Z^{\prime} Z\right)^{1 / 2} \pi \text { and } a:=(\beta, 1)^{\prime} . \tag{25.2}
\end{equation*}
$$

For a given null hypothesis value $\beta_{0}$, a one-to-one transformation of $R$ is $\left(S_{\beta_{0}}(R), T_{\beta_{0}}(R)\right)$, where

$$
\begin{align*}
& S_{\beta_{0}}(R):=\left[\left(b_{0}^{\prime} \otimes I_{k}\right) \Sigma\left(b_{0} \otimes I_{k}\right)\right]^{-1 / 2}\left(b_{0}^{\prime} \otimes I_{k}\right) \operatorname{vec}(R), \\
& T_{\beta_{0}}(R):=\left[\left(a_{0}^{\prime} \otimes I_{k}\right) \Sigma^{-1}\left(a_{0} \otimes I_{k}\right)\right]^{-1 / 2}\left(a_{0}^{\prime} \otimes I_{k}\right) \Sigma^{-1} \operatorname{vec}(R), \tag{25.3}
\end{align*}
$$

$a_{0}:=\left(\beta_{0}, 1\right)^{\prime}$, and $b_{0}:=\left(1,-\beta_{0}\right)^{\prime}$. The statistics $S_{\beta_{0}}(R)$ and $T_{\beta_{0}}(R)$ are independent. Their distributions are

$$
\begin{align*}
S_{\beta_{0}}(R) & \sim N\left(\left(\beta-\beta_{0}\right) C_{\beta_{0}} \mu_{\pi}, I_{k}\right) \text { and } \\
T_{\beta_{0}}(R) & \sim N\left(D_{\beta} \mu_{\pi}, I_{k}\right), \text { where } \\
C_{\beta_{0}} & :=\left[\left(b_{0}^{\prime} \otimes I_{k}\right) \Sigma\left(b_{0} \otimes I_{k}\right)\right]^{-1 / 2} \text { and } \\
D_{\beta} & :=\left[\left(a_{0}^{\prime} \otimes I_{k}\right) \Sigma^{-1}\left(a_{0} \otimes I_{k}\right)\right]^{-1 / 2}\left(a_{0}^{\prime} \otimes I_{k}\right) \Sigma^{-1}\left(a \otimes I_{k}\right) . \tag{25.4}
\end{align*}
$$

As shown in the following lemma, the limits of $S_{\beta_{0}}(R)$ and $T_{\beta_{0}}(R)$ as $\beta_{0} \rightarrow \pm \infty$ are

$$
\begin{align*}
& S_{ \pm \infty}(R):=\mp \Sigma_{22}^{-1 / 2} R_{2} \text { and } \\
& T_{ \pm \infty}(R):= \pm\left(\Sigma^{11}\right)^{-1 / 2}\left(e_{1}^{\prime} \otimes I_{k}\right) \Sigma^{-1} \operatorname{vec}(R) \tag{25.5}
\end{align*}
$$

where $R_{2}$ denotes the second column of $R, \Sigma_{22}$ denotes the lower right $k \times k$ block of $\Sigma, \Sigma^{11}$ denotes the upper left $k \times k$ block of $\Sigma^{-1}$, and $e_{1}:=(1,0)^{\prime}$.

Lemma 25.1 For fixed true value $\beta=\beta_{*}$ and positive definite matrix $\Sigma$, we have
(a) $\lim _{\beta_{0} \rightarrow \pm \infty} S_{\beta_{0}}(R)=S_{ \pm \infty}(R)$,
(b) $S_{ \pm \infty}(R) \sim N\left(\mp \Sigma_{22}^{-1 / 2} \mu_{\pi}, I_{k}\right)$,
(c) $\lim _{\beta_{0} \rightarrow \pm \infty} T_{\beta_{0}}(R)=T_{ \pm \infty}(R)$,
(d) $T_{ \pm \infty}(R) \sim N\left( \pm\left(\Sigma^{11}\right)^{-1 / 2}\left(e_{1}^{\prime} \otimes I_{k}\right) \Sigma^{-1} \operatorname{vec}\left(\mu_{\pi} a_{*}^{\prime}\right), I_{k}\right)$, where $a_{*}:=\left(\beta_{*}, 1\right)^{\prime}$, and
(e) $S_{ \pm \infty}(R)$ and $T_{ \pm \infty}(R)$ are independent.

Comments. (i) The convergence results in Lemma 25.1 hold for all realizations of $R$.
(ii) In the homoskedatic case, where $\Sigma=\Omega \otimes I_{k}$, we have $S_{ \pm \infty}(R)=S_{ \pm \infty}(Y)$ and $T_{ \pm \infty}(R)=$ $T_{ \pm \infty}(Y)$, where $S_{ \pm \infty}(Y)$ and $T_{ \pm \infty}(Y)$ are defined in 16.1) for the homoskedastic model.

These results hold by the following calculations. In the homoskedatic case, $\Sigma_{22}=\omega_{2}^{2} I_{k}=\sigma_{v}^{2} I_{k}$, where $\omega_{2}^{2}$ denotes the $(2,2)$ element of $\Omega$ and $\sigma_{v}^{2}:=\operatorname{Var}\left(v_{2 i}\right)$. This yields $S_{ \pm \infty}(R)=\mp\left(1 / \sigma_{v}\right) R_{2}=$ $\mp\left(1 / \sigma_{v}\right)\left(Z^{\prime} Z\right)^{-1 / 2} Z^{\prime} Y e_{2}:=S_{ \pm \infty}(Y)$. In the homoskedatic case, $\Sigma^{11}=\omega^{11} I_{k}$, where $\omega^{11}$ denotes the $(1,1)$ element of $\Omega^{-1}, \Sigma^{-1}=\Omega^{-1} \otimes I_{k}$, and $\left(e_{1}^{\prime} \otimes I_{k}\right) \Sigma^{-1} \operatorname{vec}(R)=\left(e_{1}^{\prime} \Omega^{-1} \otimes I_{k}\right) v e c(R)=R \Omega^{-1} e_{1}$, where the last equality uses the formula $\operatorname{vec}(A B C)=\left(C^{\prime} \otimes A\right) \operatorname{vec}(B)$. We have $\omega^{11}=\omega_{2}^{2} /\left(\omega_{1}^{2} \omega_{2}^{2}-\right.$ $\left.\omega_{12}^{2}\right)$ by the formula for the inverse of a $2 \times 2$ matrix, $\omega_{1}^{2} \omega_{2}^{2}-\omega_{12}^{2}=\sigma_{u}^{2} \sigma_{v}^{2}-\sigma_{u v}^{2}=\sigma_{u}^{2} \sigma_{v}^{2}\left(1-\rho_{u v}^{2}\right)$, where the first equality holds by 15.3 , and $\left(\omega^{11}\right)^{-1 / 2}=\sigma_{u} \sigma_{v}\left(1-\rho_{u v}^{2}\right)^{1 / 2} / \omega_{2}=\sigma_{u}\left(1-\rho_{u v}^{2}\right)^{1 / 2}$, where the last equality uses $\sigma_{v}=\omega_{2}$. Putting these results together gives $T_{ \pm \infty}(R):= \pm\left(\Sigma^{11}\right)^{-1 / 2}\left(e_{1}^{\prime} \otimes\right.$ $\left.I_{k}\right) \Sigma^{-1} \operatorname{vec}(R)= \pm \sigma_{u}\left(1-\rho_{u v}^{2}\right)^{1 / 2} R \Omega^{-1} e_{1}=\left(Z^{\prime} Z\right)^{-1 / 2} Z^{\prime} Y \Omega^{-1} e_{1} \cdot\left( \pm\left(1-\rho_{u v}^{2}\right)^{1 / 2} \sigma_{u}\right):=T_{ \pm \infty}(R)$.

Let $P_{\beta_{*}, \pi, \Sigma}(\cdot)$ denote the probability distribution of $R$ when $\beta_{*}, \pi, \Sigma$ are the true values. The HC model analogue of Theorem 5.1 is the following.

Theorem 25.2 Suppose $C S_{\phi}(R)$ is a CS based on level $\alpha$ tests $\phi\left(S_{\beta_{0}}(R), T_{\beta_{0}}(R)\right)$ whose test statistic and critical value functions, $\mathcal{T}(s, t)$ and $c v(t)$, respectively, are continuous at all $k \times 2$ matrices [ $s: t]$ and $k$ vectors $t, P_{\beta_{*}, \pi, \Sigma}\left(\mathcal{T}\left(S_{c}(R), T_{c}(R)\right)=c v\left(T_{c}(R)\right)\right)=0$ for $c=+\infty$ in parts (a) and (c) below and $c=-\infty$ in part (b) below. Then, for all $\left(\beta_{*}, \pi, \Sigma\right)$ with $\Sigma$ positive definite,
(a) $P_{\beta_{*}, \pi, \Sigma}\left(R \operatorname{Length}\left(C S_{\phi}(R)\right)=\infty\right)=1-\lim _{\beta_{0} \rightarrow \infty} P_{\beta_{*}, \pi, \Sigma}\left(\phi\left(S_{\beta_{0}}(R), T_{\beta_{0}}(R)\right)=1\right)$,
(b) $P_{\beta_{*}, \pi, \Sigma}\left(L \operatorname{Length}\left(C S_{\phi}(R)\right)=\infty\right)=1-\lim _{\beta_{0} \rightarrow-\infty} P_{\beta_{*}, \pi, \Sigma}\left(\phi\left(S_{\beta_{0}}(R), T_{\beta_{0}}(R)\right)=1\right)$, and
(c) if $\mathcal{T}\left(S_{c}(R), T_{c}(R)\right) \leq c v\left(T_{c}(R)\right)$ for $c=+\infty$ iff the same inequality holds for $c=-\infty$ a.s., then

$$
P_{\beta_{*}, \pi, \Sigma}\left(\operatorname{Length}\left(C S_{\phi}(R)\right)=\infty\right)=1-\lim _{\beta_{0} \rightarrow \pm \infty} P_{\beta_{*}, \pi, \Sigma}\left(\phi\left(S_{\beta_{0}}(R), T_{\beta_{0}}(R)\right)=1\right) .
$$

Proof of Theorem 25.2. The proof is essentially the same as that for Theorem 5.1 with (i) $\left(S_{\beta_{0}}(R), T_{\beta_{0}}(R)\right)$ and $T_{\beta_{0}}(R)$ in place of $Q_{\beta_{0}}(Y)$ and $Q_{T, \beta_{0}}(Y)$, respectively, using (ii) Lemma 25.1 in place of Lemma 16.1, and using (iii) the assumption of the Theorem that " $\mathcal{T}(s, t)$ and $c v(t)$ are continuous at all $k \times 2$ matrices $[s: t]$ and $k$ vectors $t$," in place of the assumption of Theorem 5.1 that " $\mathcal{T}(q)$ and $c v\left(q_{T}\right)$ are continuous at all positive definite $2 \times 2$ matrices $q$ and positive constants $q_{T}$. ." (In the argument following $\sqrt{16.3}$ ) in the proof of Theorem 5.1, the latter assumption is combined with the result of Lemma 16.1 g$)$, which implies that $Q_{\infty}(Y)$ is pd a.s. and $Q_{T, \infty}(Y)>0$ a.s. In contrast, in the proof of the present Theorem, this part of the argument is not needed because there is no restriction to positive definite matrices $q$ and positive constants $q_{T}$.) In the proof of part (c), the second last equality in 16.5 in the proof of Theorem 5.1 holds (with the changes listed in (i)-(iii) above) because the assumption imposed in part (c) of the present Theorem is the same as condition (iii) stated immediately above 16.5.

Proof of Lemma 25.1. We prove part (a) first. Dividing the components of $S_{\beta_{0}}(R)$ in (25.3) by $\left|\beta_{0}\right|$, we obtain

$$
\begin{equation*}
S_{\beta_{0}}(R)=\left[\left(\left(b_{0} /\left|\beta_{0}\right|\right)^{\prime} \otimes I_{k}\right) \Sigma\left(\left(b_{0} /\left|\beta_{0}\right|\right) \otimes I_{k}\right)\right]^{-1 / 2}\left(\left(b_{0} /\left|\beta_{0}\right|\right)^{\prime} \otimes I_{k}\right) \operatorname{vec}(R) \tag{25.6}
\end{equation*}
$$

We have

$$
\begin{align*}
\lim _{\beta_{0} \pm \infty}\left(\left(b_{0} /\left|\beta_{0}\right|\right)^{\prime} \otimes I_{k}\right) \operatorname{vec}(R) & =\left((0, \mp 1) \otimes I_{k}\right) \operatorname{vec}(R)=\mp R_{2} \text { and } \\
\lim _{\beta_{0} \pm \infty}\left(\left(b_{0} /\left|\beta_{0}\right|\right)^{\prime} \otimes I_{k}\right) \Sigma\left(\left(b_{0} /\left|\beta_{0}\right|\right) \otimes I_{k}\right) & =\left((0, \mp 1) \otimes I_{k}\right) \Sigma\left((0, \mp 1) \otimes I_{k}\right)=\Sigma_{22} \tag{25.7}
\end{align*}
$$

using $b_{0}:=\left(1,-\beta_{0}\right)^{\prime}$, where $R_{2}$ denotes the second column of $R$. Combining 25.6) and 25.7) and using the positive definiteness of $\Sigma_{22}$ gives $\lim _{\beta_{0} \pm \infty} S_{\beta_{0}}(R)=\mp \Sigma_{22}^{-1 / 2} R_{2}:=S_{ \pm \infty}(R)$, which proves part (a).

Part (b) holds by the definition of $S_{ \pm \infty}(R)$ in 25.5) because $R_{2} \sim N\left(\mu_{\pi}, \Sigma_{22}\right)$ by 25.1) and (25.2).

To prove part (c), we divide the components of $T_{\beta_{0}}(R)$ in 25.3 by $\left|\beta_{0}\right|$ to obtain

$$
\begin{equation*}
T_{\beta_{0}}(R)=\left[\left(\left(a_{0} /\left|\beta_{0}\right|\right)^{\prime} \otimes I_{k}\right) \Sigma^{-1}\left(\left(a_{0} /\left|\beta_{0}\right|\right) \otimes I_{k}\right)\right]^{-1 / 2}\left(\left(a_{0} /\left|\beta_{0}\right|\right)^{\prime} \otimes I_{k}\right) \Sigma^{-1} v e c(R), \tag{25.8}
\end{equation*}
$$

where $a_{0}=\left(\beta_{0}, 1\right)^{\prime}$. We have

$$
\begin{align*}
\lim _{\beta_{0} \pm \infty}\left(\left(a_{0} /\left|\beta_{0}\right|\right)^{\prime} \otimes I_{k}\right) \Sigma^{-1} \operatorname{vec}(R) & = \pm\left((1,0) \otimes I_{k}\right) \Sigma^{-1} \operatorname{vec}(R) \text { and } \\
\lim _{\beta_{0} \pm \infty}\left(\left(a_{0} /\left|\beta_{0}\right|\right)^{\prime} \otimes I_{k}\right) \Sigma^{-1}\left(\left(a_{0} /\left|\beta_{0}\right|\right) \otimes I_{k}\right) & =\left(( \pm 1,0) \otimes I_{k}\right) \Sigma^{-1}\left(( \pm 1,0) \otimes I_{k}\right)=\Sigma^{11} \tag{25.9}
\end{align*}
$$

where $\Sigma^{11}$ denotes the upper left $k \times k$ block of $\Sigma^{-1}$. Combining 25.8 and 25.9 and using the positive definiteness of $\Sigma^{-1}$ gives $\lim _{\beta_{0} \pm \infty} T_{\beta_{0}}(R)= \pm\left(\Sigma^{11}\right)^{-1 / 2}\left(e_{1}^{\prime} \otimes I_{k}\right) \Sigma^{-1} v e c(R):=T_{ \pm \infty}(R)$, which establishes part (c) of the lemma.

Part (d) holds by the definition of $T_{ \pm \infty}(R)$ in 25.5 because $R=\mu_{\pi} a_{*}^{\prime}+\widetilde{V}$ when $\beta=\beta_{*}$ by (25.2), $\operatorname{vec}(\widetilde{V}) \sim N(0, \Sigma)$ by 25.1, and

$$
\begin{align*}
\operatorname{Var}\left(T_{ \pm \infty}(R)\right) & =\operatorname{Var}\left(\left(\Sigma^{11}\right)^{-1 / 2}\left(e_{1}^{\prime} \otimes I_{k}\right) \Sigma^{-1} \operatorname{vec}(R)\right) \\
& =\left(\Sigma^{11}\right)^{-1 / 2}\left(e_{1}^{\prime} \otimes I_{k}\right) \Sigma^{-1} \Sigma \Sigma^{-1}\left(e_{1} \otimes I_{k}\right)\left(\Sigma^{11}\right)^{-1 / 2} \\
& =I_{k} \tag{25.10}
\end{align*}
$$

Part (e) holds because $S_{ \pm \infty}(R)$ and $T_{ \pm \infty}(R)$ are jointly normal with covariance

$$
\begin{align*}
\operatorname{Cov}\left(S_{ \pm \infty}(R), T_{ \pm \infty}(R)\right) & =\operatorname{Cov}\left(\mp \Sigma_{22}^{-1 / 2}\left(e_{2}^{\prime} \otimes I_{k}\right) \operatorname{vec}(R), \pm\left(\Sigma^{11}\right)^{-1 / 2}\left(e_{1}^{\prime} \otimes I_{k}\right) \Sigma^{-1} \operatorname{vec}(R)\right. \\
& =-\Sigma_{22}^{-1 / 2}\left(e_{2}^{\prime} \otimes I_{k}\right) \operatorname{Var}(\operatorname{vec}(R)) \Sigma^{-1}\left(e_{1} \otimes I_{k}\right)\left(\Sigma^{11}\right)^{-1 / 2} \\
& =I_{k} . \tag{25.11}
\end{align*}
$$

This implies that $S_{ \pm \infty}(R)$ and $T_{ \pm \infty}(R)$ are independent, which proves part (e).

Marmer gratefully acknowledges the research support of the SSHRC via grant numbers 410-2010-1394 and 435-2013-0331. The authors thank Marcelo Moreira, James MacKinnon, a co-editor, and three referees for helpful comments.

[^1]:    ${ }^{1}$ See Table SM-I in the Supplemental Material for other parameter combinations.

[^2]:    ${ }^{2}$ See Table SM-I in the SM.

[^3]:    ${ }^{3}$ Davidson and MacKinnon (2008) do not consider the probabilities of unbounded CS's or provide optimality results for tests, which are the main focus of this paper.

[^4]:    ${ }^{4}$ The density of this distribution is given in 12.4 in the SM.

[^5]:    ${ }^{5}$ We have $E Q_{S T}=E S^{\prime} E T$ by independence of $S$ and $T, E Q_{S T}=0$ under $H_{0}$ because $E S=0$, and $\lim _{\left|\beta_{0}\right| \rightarrow \infty} E Q_{S T}=0$ under $\beta_{*}$ because $E T=\mu_{\pi} d_{\beta_{*}}\left(\beta_{0}, \Omega\right), \lim _{\beta_{0} \rightarrow \pm \infty} d_{\beta_{*}}\left(\beta_{0}, \Omega\right) \rightarrow \mp r_{u v} / \sigma_{v}$ by Lemma $15.1(\mathrm{e})$ in the SM, and $r_{u v}=0$ when $\rho_{u v}=0$.

[^6]:    ${ }^{6}$ These results hold because (i) the AR test strictly fails to reject $H_{0}: \beta=\beta_{0}$ when $S^{\prime} S<\chi_{k, 1-\alpha}^{2}$ iff $b_{0}^{\prime} Y^{\prime} P_{Z} Y b_{0}<$ $b_{0}^{\prime} \Omega b_{0} \chi_{k, 1-\alpha}^{2}$ iff $a \beta_{0}^{2}+b \beta_{0}+c<0$, where $a:=y_{2}^{\prime} P_{Z} y_{2}-\omega_{2} \chi_{k, 1-\alpha}^{2}, b:=-2\left(y_{1}^{\prime} P_{Z} y_{2}-\omega_{12} \chi_{k, 1-\alpha}^{2}\right)$, and $c:=y_{1}^{\prime} P_{Z} y_{1}-$ $\omega_{1} \chi_{k, 1-\alpha}^{2}$, using 2.3 and some calculations, and (ii) the AR CS has infinite length when $a<0$. When $a=0$, the AR CS has infinite right length if $b<0$, infinite left length if $b>0$, infinite length if $b=0$ and $c \leq 0$, and finite length if $b=0$ and $c>0$. For related results, see Dufour and Taamouti (2005).

[^7]:    ${ }^{7}$ The simulation standard deviations of the DPIL's are in the range of $[.0000,0014]$ with most being in the range of [.0004, .0012], see Table SM-I in the SM.
    ${ }^{8}$ Table SM-I in the SM shows that the differences in probabilities that the AR and POIS2 CS's have infinite length are very large for large $\rho_{u v}$ values for some $\lambda$ values. For example, for $\rho_{u v}=.9$, they are as large as $.084, .196, .280, .353, .422$ for $k=2,5,10,20,40$, respectively, for some $\lambda$ values. As shown above, $A R=P O I S 2$ when $\rho_{u v}=0$, so the differences are zero in this case and they increase in $\left|\rho_{u v}\right|$ for given $(k, \lambda)$.

[^8]:    ${ }^{9}$ See Table SM-II in the SM for how the maximum PD's over $\beta_{0}$ vary with $\lambda$ for the $\left(\rho_{u v}, k\right)$ values in Table II.

[^9]:    ${ }^{10}$ Note that $\left(\beta_{*}, \lambda\right)$ and $\left(\beta_{2 *}, \lambda_{2}\right)$ in this paper correspond to $\left(\beta^{*}, \lambda^{*}\right)$ and $\left(\beta_{2}^{*}, \lambda_{2}^{*}\right)$ in AMS.
    ${ }^{11}$ The formulae in (6.3) and (14.2) only hold for $\beta_{*} \neq \beta_{A R}$, where $\beta_{A R}:=\left(\omega_{1}^{2}-\omega_{12} \beta_{0}\right) /\left(\omega_{12}-\omega_{2}^{2} \beta_{0}\right)$ provided $\omega_{12}-\omega_{2}^{2} \beta_{0} \neq 0$ (which necessarily holds for $\left|\beta_{0}\right|$ sufficiently large because $\omega_{2}^{2}>0$ ).

[^10]:    ${ }^{12}$ Throughout, $\beta_{0} \rightarrow \pm \infty$ means $\beta_{0} \rightarrow \infty$ or $\beta_{0} \rightarrow-\infty$.

[^11]:    ${ }^{13}$ The proof of Comment (v) to Theorem 5.1 is the same as that of Theorem5.11 a) and (b) with $\left[S_{\beta_{0}}(Y), T_{\beta_{0}}(Y)\right]$ and $T_{\beta_{0}}(Y)$ in place of $Q_{\beta_{0}}(Y)$ and $Q_{T, \beta_{0}}(Y)$, respectively.

[^12]:    ${ }^{14}$ The formula $\bar{\beta}:=\left(\widetilde{\omega}_{2} / \widetilde{\omega}_{1}\right) \widetilde{\beta}$ in 21.2 comes from $\bar{y}_{1}:=\widetilde{y}_{1} / \widetilde{\omega}_{1}=\left(y_{2} \widetilde{\beta}+u\right) / \widetilde{\omega}_{1}=y_{2} \widetilde{\beta} / \widetilde{\omega}_{1}+u / \widetilde{\omega}_{1}=\left(y_{2} / \widetilde{\omega}_{2}\right) \widetilde{\beta}\left(\widetilde{\omega}_{2} / \widetilde{\omega}_{1}\right)$ $+u / \widetilde{\omega}_{1}=\bar{y}_{2} \bar{\beta}+\bar{u}$, where the last equality holds when $\bar{\beta}:=\left(\widetilde{\omega}_{2} / \widetilde{\omega}_{1}\right) \widetilde{\beta}$ and $\bar{u}:=u / \widetilde{\omega}_{1}$.

[^13]:    ${ }^{15} \mathrm{In}$ Tables II and SM-II, $\rho_{u v}=\rho_{\Omega}$ for all $\beta_{0}$ values because the true value $\beta^{*}=0$.

[^14]:    ${ }^{16}$ We thank Marcelo Moreira for suggesting that we consider the $C L R 2_{n}$ tests considered in this section.
