Theory and Reality of Cryptocurrency Governance

Paper for the 2019 ASSA Annual Meeting
Atlanta GA January 4 – 6, 2019
Paper Session: Technological Change and Social Provisioning
Hosted by the Association for Evolutionary Economics (AFEE)
Friday, Jan. 4, 2019 2:30 PM - 4:30 PM
Hilton Atlanta, Crystal F

Antoon Spithoven*

Abstract: I analyze cryptocurrency ecosystems with Elinor Ostrom’s meta-framework for self-governance. I conclude that Bitcoin falls short in its self-governing ambitions, while cryptocurrency software protocols and blockchain technologies have potentialities within ‘permissioned’ peer-to-peer private or hybrid networks. However, regulation and supervision by trusted third parties are required.

Key words: cryptocurrency, governance

JEL codes: B52, E4, E5, L5

Satoshi Nakamoto (2008, 1) developed “an electronic payment system based on cryptographic proof instead of trust” (emphasis added), allowing any two willing parties to transact directly with each other without the need for a trusted third party (... Within this system, a) peer-to-peer network timestamps transactions by hashing them” cryptographically into a blockchain. “A blockchain is, essentially, a way of moving information between parties over the Internet and storing that information and its
transaction history on a network of computers.” Public blockchains are claimed to prevent cheating and to bypass extractive external institutions (Halpern 2018, 54). As such, the network might be interpreted as a self-governing system. It fits in with the libertarian-inspired Silicon Valley dream that computer networks can create order in society without transaction cost increasing human control.

Several cryptocurrencies (coins and tokens) have been created and disappeared since the launch of the Bitcoin.\(^1\) Coins, such as Bitcoin, are developed as a general medium of exchange. Tokens or Initial Coin Offerings (ICO’s) appear under the flag of fundraising for development and provision of a specific new service or product.\(^2\) Getting a cryptocurrency accepted is assumed to be subject to the market mechanism. However, the fact remains that one must convince the public that programmers will deliver what is promised and that the cryptocurrency will have value.

Elinor Ostrom’s (2005) Institutional Analysis and Development (IAD) model for self-governance provides handles to answer the question if the cryptocurrency consensus algorithm is a sufficient substitute for trust in a peer-to-peer electronic payment system (Smith and Crown 2016).\(^3\) Though self-governance may suggest a libertarian disposition, Ostrom was not a libertarian or a supporter of a stateless society.\(^4\)

**Self-governing systems**

Ostrom (2005, 99, 103) assumed individuals to be basic units of decision-making. Her game-theoretic analyses are based on assumptions concerning: 1) acquired partial or complete information, its asymmetric or symmetric distribution, and its imperfect or perfect processing; 2) valuation processes (rational egoism, trust or reciprocity), and; 3) processes of selection (maximizing, satisfying, or using diverse rules of thumb).
Ostrom (1992, 67-79; 2005, 59, 259) integrated eight self-governance conditions in the IAD model to analyze governing the commons as a more efficient governance structure than markets and governments. These self-governance conditions concern: clearly defined boundaries (objectives) and memberships, proportional incentives, actively auditing monitors, collective choice arrangements, graduated sanctions, conflict resolution mechanisms, rights that are recognized by “external governmental authorities”, and nested local rules within governmental rules at regional and national levels. I analyze cryptocurrency ecosystems in view of conditions one to three.

Cryptocurrency Ecosystems

Cryptocurrency ecosystems may include: the initiators, the codebase, programmers, miners, middlemen, customers, the media, and governments.\textsuperscript{5} See Figure 1.

\textit{Initiators of cryptocurrency and Internet platforms}

The sales pitch of cryptocurrency organizations is that “money supply should not be used as an instrument of monetary policy as inflation destroys value & encourages unsustainable consumption” (Bitcoin Foundation 2018b). Therefore, governments should have to become disabled to smooth business cycles and this can be achieved by setting supply at a final limit or allowing for a steady increase.

Organizations behind cryptocurrency influence their governance. For example, the Bitcoin Foundation (2018a, 2018b, 2018c)—whose directors have a personal interest in blockchains—and
other non-profit organizations coordinate efforts of cryptocurrency communities such as funding of core programmers, lobbying upon legislators to make cryptocurrency to a success, and developing a platform. Values expressed by the Bitcoin Foundation concern privacy, guaranteed financial access, decentralization (“centralization of money supply leads to corruption & exploitation”), autonomy, financial inclusion, and stable money supply.

Cryptocurrency Internet platforms (such as bitcoin.org) are owned by the community but are likely to be influenced by sponsors (for instance, the exchange Paxful) and the Website maintainer. The platforms give customers and providers of services access to public ledgers. Customers are consumers and businesses (such as, traders). Providers of processing services are programmers and validators of transactions (the so-called miners). Providers of financial services are middlemen such as wallet providers, exchanges, and mixers. Mixers lump transactions together to obfuscate the identity of customers.

*Cryptocurrency are rooted in a code.*

The software behind the Bitcoin payment system is a common. Open-source license enables everyone to propose changes to the software, while trust is assumed to be established through decentral, distributed, public ledgers in the form of a blockchain: a system to share information and to store the history of transactions on a computer network (Halpern 2018, 54). The blockchain is assumed to foster efficiency by lowering transaction cost through consensus algorithms, minimizing counterparty risk, reducing settlement times, eliminating unnecessary middlemen, improving contractual term performance, improving regulatory control, and increasing transparency for regulatory reporting.
The basic code of a public ledger encloses: the rules for transactions (protocol for sending, receiving, and recording value using cryptographic methods), hash protocols (linear or tree-based protocols), block attributes (block version number, timestamp, hashes—that is, input strings of any length are transformed in output strings of a fixed length), and consensus mechanisms. To determine which blockchain is valid there are two coordination rules: first the longest blockchain is generally assumed to be reliable, and second, checkpointing—that is, a mined block must be linked (not to genesis one but) to a more recent blockchain (Abramaowicz 2016, 374-375).

The Bitcoin protocol serves several functions. The protocol provides a financial reward to miners “for generating a block of transactions to add to the end of the block chain (. . . Besides, they may) receive transaction fees from transferors of bitcoins, who voluntarily include these fees in their transactions to encourage miners to include the transactions in a block” (Abramowicz 2016 376). Transactions are by design irreversible, even if a contract is incomplete. Another function of the Bitcoin protocol concerns one’s privacy. Customers are not required to register one’s real identity.

In fact, the codebase is constantly evolving (new tools, functions and services are developed to improve security and acceptance), might become hacked, and may results in hard forks. Forking indicates “inconsistencies in the replicas in the network” (Decker and Wattenhofer 2013, 1; Abramaowicz 2016, 372), and might be harmful for the relevant cryptocurrency (Gervais et al. 2014). Inconsistencies “facilitate an attacker that attempts to rewrite transaction history” and may undermine trust in the cryptocurrency (Decker and Wattenhofer 2013, 1). A no-forking guarantee requires a patented codebase rather than an open source codebase.
The bitcoin programmers centrally coordinate the Bitcoin protocol (Abramaowicz 2016, 367). They regulate the Bitcoin through their decisions regarding forking and blocking interactions from specific addresses (coin tainting) (Gervais et al. 2014). Some forks might be malicious and serve the financial interests of programmers who set aside a certain amount of coins as payment for themselves. A feature of the Bitcoin Gold is that the developers placed 100,000 coins in a special endowment that is said to be used for the development of the Bitcoin Gold ecosystem, including the payment of developers.

Core programmers of the source code may benefit from volunteers by making the software available freely to everyone. Regarding the Bitcoin there is a concentration of programmers who contribute to the codebase and a concentration of commenters who propose changes to the codebase (Azouvi, Maller, and Meiklejohn 2018). It may result in different versions of the coin involved.6

Miners

An electronic payment network such as Bitcoin is an institution that “creates and enforces property rights (..., and) that can resolve only one type of decision-making: whether purported transfers (...) will be validated and added to (...) the block chain” (Abramaowicz 2016, 361). Labor of miners is involved to verify legitimacy of transactions. They are rewarded with coins “for their services in addition to” possible transaction fees (Evans 2014, 12).

Miners provide network security through either Proof of Work (PoW) or Proof of Stake (PoS) ((Rosic 2017; Halpern 2018, 54). The difference between PoW and PoS concerns who creates a new block: the miner who is the first to solve the math problem that is involved in creating a new block respectively the miner who has the most coins can create a new block. The PoW requires high
investments (large-scale operations), is time consuming, and energy inefficient. It rises the risks of engaging in the form of mining in which payments are awarded randomly. Pools of miners emerged to diversify random payment risks (Evans 2014, 18). (New) miners may join the pool and might be charged a membership fee. Some pools disclose and share transaction fees. The PoS is subject to monopolization by means of organizations with big stakes (owners of a large share in the volume of available coins).

A colluding power block of miners may “effectively control the confirmation of all transactions occurring in the system. This includes preventing transactions from being executed, approving a specific set of transactions and double-spending transactions” (Gervais et al. 2014: 55). The pool also prescribes the type of protocol that your computer follows. Finally, a power block of more than fifty percent may create a new hard fork (Gruber 2013, 163).

Quantum computers might solve the time and energy consuming mining process, but might create other challenges such as the possibility to rewrite the whole history of a blockchain. This undermines trust. Quantum computers might enable people to forge transactions and to steal coins unless better signature schemes are developed.

Middlemen: wallets, exchanges, mixers

Cryptocurrencies require a whole set of intermediaries in the form of firms that provide processional and financial services. Ironically, also the criticized banking system is involved: traders use virtual stablecoins (for example, Tether, TrueUSD, PAX, AUD (Australian dollar)), which are pegged to fiat currency or gold, for trading cryptocurrency on exchanges.
According to Rainer Böhme et al. (2015, 222) currency exchanges and digital wallet services are subject to failures; mixing “protocols are usually not public” which enables mixers, who disconnect originating and receiving addresses, to run away with funds; all middlemen charge commissions or fees, and; consumers and heirs-at-law may lose coins (because of crashed/hacked computers respectively decease). Additionally, Böhme et al. (2015, 226) mention: trade in large amounts (in the form of dumping or spoofing) influences the price of the currency; closing of exchanges; “and legal and regulatory risk”.

Customers

Customers feed the network dynamics. Their transactions, behaviors, and risks to which they are exposed result in adopting, rejecting, adapting or even hard forking of cryptocurrency. Among other things, the volatility of coin value did prevent cryptocurrencies to become a general-purpose currency as proclaimed (Irwin 2018).

The value of coins fluctuates because expectations over demand are influenced by a myriad of factors. Examples of these factors are: there is no third party to intervene to stabilize the value, new cryptocurrency or disappearing cryptocurrency may influence the price of other currency, and customers of cryptocurrency are multiple in kind. Demand for a specific cryptocurrency may rise because customers may use cryptocurrency not only for lawful transactions, but also for tax evasion, money laundering, extortion, prostitution, human trafficking, speculation, and trade in drugs and weapons (Gruber 2013).

Other reasons that cryptocurrencies are ill-suited as a medium of exchange or as a reliable unit of account, are: transaction risks (bankruptcies of financial service providers, difficult to use),
uncompetitive applications (low transaction speed, delay of verification), operational risk (operator errors, malware, security flaws, Platform lock-in of programmers), privacy-related risk (Evans 2014), and high fees.

Additionally, privacy is after all difficult to guarantee. One’s identity might become revealed through one’s delivery address for a purchase of a commodity (Böhme et al. 2015, 221), and through one’s cryptocurrency-exchange account (Liedel 2018, 113). To stay under the radar customers may use the after each transaction automatically changed wallet address. They also may use software providing anonymity like Tor, or; in exchange of a fee, they may call in poolers of transactions (Böhme et al. 2015).

The Media

The media have the power to enable public discourse, to redirect the public discussion on pros and cons of cryptocurrency, and to influence the price. Investigative journalism might provide customers and service providers with critical information regarding potentialities of new technologies the misuse of these technologies, and existing or lacking regulations. However, (social) media are subject to hypes, fake news, and news on money laundering, speculation, and manipulation by traders. This might disable their monitoring and information function. Their focus on irregularities may distract the public from potentialities of the blockchain technology (Papadopoulos 2015, 128).
Cryptocurrency adherents believe that public ledgers make regulating and supervising by (extractive) agencies obsolete. Their claim is misplaced because blockchain technology concerns only registering and validation of a transaction. Participants of cryptocurrency ecosystems are unable to monitor and sanction misbehaviors. According to Sarah Gruber (2013, 162), “the Bitcoin ecosystem is far less trustworthy than the banks that the Bitcoin proponents denounce as untrustworthy.”

Cryptocurrencies and their blockchain technology have gained that much popularity that governments cannot simply forbid them. At the risk of suffocating innovation and the chance to boost innovation by legitimizing it (Hughes and Middlebrook 2015, 499), the use of cryptocurrencies and the supply of services based on cryptocurrencies should become regulated and supervised for the sake of fighting crime, protection of traditional infrastructures, and protection of consumers. Additionally, regulation and supervision are also desired to safeguard the financial system. Namely, the traditional financial system is challenged by cryptocurrency. Cryptocurrency may “transform the monetary system as a whole” (Papadopoulos 2015, 128).

To integrate public ledgers in properly operating markets, blockchain technologies must be nested in a whole set of institutions which not only addresses rights, duties, liberties, and exposures of all parties involved, but also enable monitoring, sanctioning, and conflict resolution. Regulation of intermediaries to cryptocurrency transactions might become inspired by “regulations governing existing payment mechanisms” so that cryptocurrency transactions might become recorded, verified and monitored (Hughes and Middlebrook 2015, 498, 513).

Prudential and market regulation of cryptocurrency are scarcely out of the egg. Existing regulation of cryptocurrencies concentrates on public purposes, among which tax collection and fighting criminal activities and monetary losses. Governmental authorities focus on regulating especially cryptocurrency middle-men (Hughes 2017, 21). Examples of these type of regulations are:
1) the requirement in the United States of America to register with the Financial Crimes Enforcement Network, or; 2) the requirement to register with the Commodity Futures Trading Commission, and; 3) the reporting requirements of the Bank Security Act for “money transmission services (... including) substitutes for currency” (Gruber 2013, 173). However, federal regulations are not specified to cryptocurrency, “which makes enforcement of any new legal framework tenuous” (Hughes 2017, 1).

Cryptocurrency lack default rules that “apply in the absence of negotiated contracts or when negotiated contracts are silent on the issue in question” (Hughes and Middlebrook 2015, 502, 507, 549; Tu 2018, 538-539). Codification might be based on assessing existing practices such as Bitlicense in New York (Claasen 2017). Some of existing regulations of traditional currencies might be extended to cryptocurrencies. For example, the Internal Revenue Service approaches cryptocurrency as property—which allows capital gains and the value of the property to be taxed—but might reconsider cryptocurrency as a currency (Liedel 2018) or as collateral (Tu 2018).

The public blockchain technology is an example of innovation that the Framers never could foresee. Blockchain technology is thought to enable a reliable and decentralized record keeping of “virtually everything of value” (Liedel 2018, 110). It challenges traditional property rights: blockchain ownership is shared ownership, while blockchain technology enables to issue, own and manage digital assets. It creates a new pitch that may transform the concept of ethical business or corporate social responsibility. It might become federally regulated in accordance with the Commerce Clause by relaxing the interpretation of the Commerce Clause (Kennedy’s 1995, 6, 13).

According to the Tenth Amendment of the U.S. Constitution: "The powers not delegated to the United States by the Constitution, nor prohibited by it to the State, are reserved to the State
respectively, or to the people.” In line with this, several “states in the U.S. are currently working on legislation specifically for cryptocurrencies” (Hughes 2017, 21).

In addition to regionally regulating cryptocurrencies, governments should also cooperate internationally to combat the misuse of cryptocurrency, and to protect the cryptocurrency features, because customers that transfer cryptocurrency “may fall outside the regulatory scope” of a nation’s law, or because exchanges may move “to countries with less regulation”. Probably governments also must prohibit mixing services and the Tor network (Gruber 2013, 139-140, 189,193).

Conclusion and discussion

The application of Ostrom’s criteria for self-governance shows that cryptocurrency require more than computer algorithms. Hashing power is concentrated in mining pools. Providers of processing services are more concentrated and less transparent than the Bitcoin-design suggests. Providers of financial services are subject to several failures. Multifarious users may game cryptocurrency ecosystems to reap (illegally) benefits. Although organizations behind peer-to-peer networks may enforce improvements on incentives and governance, regulation and supervision by external institutions are desired. Without strong external regulation, cryptocurrency may resemble Veblenian (predatory) markets.

Although blockchain technology does not yet deliver what is suggested with its application in cryptocurrency, it is nevertheless promising. It might be used to digitally register all kinds of transactions. Vested interests may turn to permissioned private blockchains—that is, blockchains for clearly defined objectives and memberships, for example, firms—or to hybrid blockchains (consortia, for example the Blockchain Diamond).
It will take a long time before blockchain is going to fundamentally influence society and economy. As is known from the institutional literature, new technologies may incite resistance. Additionally, governments need time to develop laws that legitimize and constrain application of blockchain technology. Furthermore, regulation is a devil of a job: Different levels of government should cooperate and fit international agreements to local circumstances. Finally, given appropriate cultural conditions, the time needed to familiarize and to adapt oneself to technologies is determined by their novelty and complexity (use, reach, process-substitution and system-transformation) (Iansiti and Lakhani, 2017).
Endnotes

1) At 4-25-2018, there are 1591 cryptocurrency (coins and tokens) traded on 10635 markets. Until 11-25-2018, 798 currency (of which 183 are non-mineable) were introduced, and 318 currency disappeared. (Mineable currencies, such as the Bitcoin, are currencies which are rewarded to individuals who maintain the system—that is, the miners. Pre-mined currencies, such as the Ripple that has a founders’ retention of 20 percent, are currencies which developers generate all at the start of a project and which from then on are distributed in the market.) The number of markets (some might be behind new ICO’s) increased to 15687, while >1100 disappeared (https://coinmarket.com). The rise in the number of cryptocurrencies (30%) and exchanges (48%), indicate respectively a new financing and revenue model, while the number of failing ICO’s (20%) and disappearing exchanges either reflect a Ponzi scheme or indicate that the public exercises restraint and or that some releases are fraudulent in character. The revenue options increased with the opening of Bitcoin Futures in December 17, 2017. Spoofing might have boosted the prices. The sharp drop in value until February 7, 2018 might indicate a dumping of cryptocurrency by traders. In November 2018, the marketcap again decreased sharply. This time, the might have occurred due to a fall in trust in the Bitcoin with the launch of a new hard fork of the Bitcoin Cash, namely the BitcoinSV (Satoshi Vision).

2) The ICO’s “can be traded for services, once the business is operational—whenever that is—or traded for crypto- and other currencies” (Halpern 2018, 56).
3) Ostrom (1992) elaborated her model for analyzing self-governance of non-tradeable resources. The model might be extended to tradeable goods as well.

4) First, Ostrom (2005, 24) claims that commons represent not private but common-pool resources. Second, commons are one of many possible efficient governance structures. She (2005, 249, 268) allows governmental authorities to step in.

5) Due to limited space, I focus on differences between theory and practice, while differences in practice (see Hileman and Rauchs 2017) cannot be dealt with.

6) There exists about forty variants of the Bitcoin (https://coinmarketcap.com/), most of them have a maximum supply of 21 million coins. Bitcoin Gold (5 % is set aside as a bonus), Bitcoin Cash, and Bitcoin Silver are three examples of a hard fork of the Bitcoin. Namecoin and Litecoin are based on the Bitcoin technology, while Dogecoin is a fork of Litecoin (Evans 2014, 16).

7) The blockchain, either or not adapted for invitation-only peer-to-peer networks, could be used to facilitate transactions of several kinds of digitized data, such as property. Also, smart “contracts could be written and stored on the blockchain.” A smart contract might be a loan: “I send you some money, and your account automatically pays it back, with interest” (Halpern 2018, 54, 56). The task performance might change of notaries, lawyers, auditors, administrators, and arbitrators are involved in agreeing, controlling and enforcing contracts. For example, auditors may shift their attention to internal control mechanisms, or their employment might become threatened through the blockchain technology.

Figure 1: The ecosystem of minable currency

Theory (role of players in minable currency):

- Provides access
- Determines the incentive and governance system of a currency
- Establishes trust in currency through distributed ledgers
- Guarantees privacy
- Everybody may propose changes
- Provides network security through Proof of Work or Proof of Stake

The players:

- Internet platform
- Codebase: the protocols are supported by a community or firm based
- Programmers
- Miners

Reality:

- Board directors of the organization behind the Internet platform have a personal interest in blockchains
- Only a few administrators are entitled to change the code
- Resolves only one type of decision; adding validated transfers to a blockchain
- Privacy is difficult to guarantee
- Only a small group of programmers propose the majority of changes
- Some programmers are paid
  - They may set coins aside as payment for themselves
- Hashing power is concentrated through pooled mining
  - "Voluntary" transaction fees
