WHAT HAPPENS AFTER YOU OVERPAY FOR A HOUSE

Weifeng Wu and Eric Rosenblatt

Fannie Mae

December 01, 2018

◆ロト ◆昼下 ◆臣下 ◆臣下 ○日 ○○○

- Appraisal is usually required for every mortgage in the US.
- ② Appraisers are assumed to be professional and objective.
- However, appraisers do have a misaligned incentive, a problem well known in the industry but new to average home buyers.
- Hence, 95% of appraisals are simply confirming that the contract is done right.

< □ > < (四 > < (回 >) < (u >

- AVM is not new for mortgage industry professionals.
- AVM has different methodologies, and may be pretty off the mark too.
- AVM uses actual home sales, so could be inflated as well because if slow-learning Bayesian.
- However, AVM has less human intervention from the lenders.
- Hence, AVM could be very useful benchmark for the borrowers.

(日) (四) (문) (문) (문)

Preview of the results: if one overpays compared to the benchmark,

- s/he is much more likely to become serious default (6-month delinquent within five years of loan acquisition);
- and the magnitude of such effect is huge: in 2007, the top decile of overpayment defaults at 23% while the bottom at 17%.
- if s/he is lucky and survives until the next time the house is sold, s/he will realize less profits compared to her or his peers.

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ 臣 のへで

This holds true for various kinds of AVMs, even a simple mark-to-market valuation.

Four Benchmarks

- Origination AVM
- Contemporaneous MTM

(日) (图) (문) (문) (문)

- Post-Acquisition AVM
- Ex Post MTM

Four Benchmarks

for each acquisition year,

- run regression to predict risk using all factors other than the overpayment
- for each decile, select loans that have similar risk.
- in the end, each decile will have the same number of loans,
- and more importantly, have the similar distribution of predicted risk

Difference in actual default rate <= difference in overpayment

Next time the house is sold?

- find loans that we know they were sold as a arms length transaction
- regroup them and divide them into 10 deciles according to the overpayment
- compute the expected profit which is the neighborhood price change
- do a propensity score matching, using the expected profit as the propensity score
- compare the actual profit across overpayment deciles in the matched sample

Figure: Overpay => Less Profits

◆□▶ ◆□▶ ◆三▶ ◆三▶ 三三 のへで

Empirically we demonstrate that compared to different AVMs, borrowers who overpay

- are more likely to serious default in the future
- and are also more likely to receive less profit from home ownership.
