Abstract

We study how local and federal responsibilities shape immigration enforcement outcomes. Tracking the movement of unlawfully present immigrants along the deportation pipeline, we propose a framework to decompose the variation in deportation rates between federal and local enforcement efforts, and the arrestee-pool composition. This allows us to recover local responses to changes in federal enforcement intensity, establishing that among urban counties, 80% exhibit strategic substitutabilities. Following a 2011 shift in federal enforcement priorities, local enforcement collaboration increased while alignment of local-federal preferences decreased. The federal level became very effective in directing its efforts toward counties where it expected higher collaboration.

Keywords: Immigration enforcement, Secure Communities, federalism, law enforcement, crime.

We are also grateful to Daron Acemoglu, Elizabeth Cascio, Frank DiTraglia, Karam Kang, Mónica Martínez-Bravo, Pablo Montagnes, Joan Monras, Bernardo Silveira, Daniel Thompson, Petra Todd, Ken Wolpin, and to participants at the Politics, Race, and the Economy session of the 2019 ASSA meetings, USC, Emory, Princeton, the University of Western Ontario, Universidad Javeriana, Universidad Católica de Chile, the Chicago FED, the 2019 NBER Political Economy meeting, the Workshop on the Political Economy of Development and Conflict at Universitat Pompeu Fabra, the 2019 LACEA-RIDGE Political Economy workshop, the 2019 Barcelona GSE summer forum, the 2019 Petralia Political Economy conference, and the 2019 Wallis Political Economy Conference for their suggestions. We also thank the Institute for Quantitative Theory and Methods at Emory University for its financial support, and the Transactional Records Access Clearinghouse (TRAC) at Syracuse University for sharing their database with us as fellows of the center. We thank Ashwin Kambhampati for excellent research assistance. The views expressed in this paper are not necessarily those of the Federal Reserve Bank of Chicago or the Federal Reserve System.
1 Introduction

A long tradition in the social sciences has studied the allocation of tasks across different levels of government in the context of federalism (Hooghe and Marks (2003); Inman and Rubinfeld (1997b); Oates (1999)). Scholars have emphasized that the extent of decentralization should be driven by the degree of preference heterogeneity and the salience of local information, because the social value of locally tailored policies must be traded-off against the benefits of coordination or scale economies in public goods provision (Tullock (1969)). From a positive standpoint, the existence of such trade-offs suggests we should observe more decentralization and more conflict where there is more preference heterogeneity (Besley and Coate (2003); Strumpf and Oberholzer-Gee (2002)), and increased spatial sorting across jurisdictions where policy is more decentralized, as people will then find it valuable to vote with their feet (Tiebout (1956)).

Other important aspects of federalism, however, have not received as much attention. In several policy dimensions, rather than allocating disjoint tasks to different levels of government, both the federal and the local levels undertake overlapping actions that jointly determine policy outcomes (either because it is difficult for the federal level to implement policy without local-level aid\(^1\), or because the local level is able to exercise some discretion). Moreover, the local level is often not just an agent of the federal level. In the US this is established in the 9th and 10th Amendments to the Constitution, which allocate to the states and the people any rights not explicitly delegated to the federal government. In such circumstances, we may expect coordination to take place when local and federal preferences are aligned. Otherwise, the local level may partly or fully undo the actions of the federal level.\(^2\) As such, variation in the extent of preference alignment between levels of government should be a major driver of policy-outcome heterogeneity across jurisdictions, and of the success or failure of the policies themselves.

In this paper we explore precisely this possibility by studying immigration enforcement policy in the US. Immigration enforcement is an ideal setting to study strategic interactions under federalism. Although from a legal standpoint immigration policy falls under the purview of the federal government\(^3\), in practice many margins of its enforcement are directly and indirectly affected by local-level decisions. Moreover, demographics, partisanship, and proximity to bor-

\(^1\)In Federalist No. 44, James Madison recognized that in many instances the federal government would be dependent upon state and local governments to carry out policy, which in his view justifies the Supremacy Clause of the Constitution (Madison (1788)). In the case of immigration enforcement which will concern us here, while the payroll of ICE in 2010 was approximately 20 thousand employees, the number of state and local law enforcement officers across the US was more than 800 thousand (Reaves (2010)).

\(^2\)De Tocqueville raised this issue early on: “Among the weaknesses inherent in all federal systems, the most obvious of all is the complexity of the means it employs. This system necessarily brings two sovereignties into confrontation” ((DeTocqueville, 2003 [1840], p.192)).

ders all shape local preferences over immigration policy. As a result, there is ample variation in the extent of alignment of preferences over immigration enforcement between the federal and the local levels (counties in the US).

Strategic interactions between levels of government arise in many settings beyond immigration enforcement, such as school funding, tax enforcement, the administration of the foster care system, or environmental protection and regulation just to mention a few (see Cascio et al. (2013); Mann (2011); Rechtschaffen and Markell (2003)). A central challenge in any of these settings is to understand the nature of the strategic environment, and to distinguish the different margins of enforcement from each other and from the underlying economic environment shaping both policy choices and policy outcomes. Perhaps except for Agarwal et al. (2014); Bohn et al. (2015); Fredriksson and Mamun (2008); Knight (2002), there is scant empirical literature exploring these issues or highlighting how strategic responses across levels of government are key to understand heterogeneity in policy outcomes.

We consider the enforcement of immigration policy under the Obama administration during the period of operation of the Secure Communities program. Under this program, whose rollout began under the George W. Bush administration, the fingerprints of every person arrested by local police are automatically sent to the Department of Homeland Security’s Immigration and Customs Enforcement agency (ICE), where they are automatically compared with a variety of law enforcement databases to establish the immigration status of the arrestee. This allows ICE to locate potential targets of deportation, without requiring the acquiescence of local law enforcement. ICE then has full discretion to issue or not a detainer request to the jail where the arrestee is being held. The detainer asks local law enforcement to hold the arrestee for up to an additional 48 hours, giving ICE time to take the arrestee into federal custody. At this point a deportation process may begin. Between 2009 and 2014 under the Secure Communities program, ICE issued 485 thousand detainers, held in custody 479 thousand people (with and without issued detainers), and removed 396 thousand individuals.

The period covered by the Obama administration is especially convenient for our purposes because midway into the eight-year term, the administration undertook a major shift in immigration enforcement policy at the federal level. The new guidelines explicitly advocated a shift in the focus of federal enforcement efforts away from the prosecution of unlawfully present immigrants accused of misdemeanors and minor crimes, and towards those accused of serious crimes. Trends in aggregate federal immigration enforcement outcomes indeed show a dramatic reversal following the policy change, allowing us to leverage this change in federal immigration enforcement intensity to trace the heterogeneous responses of the local level to it.

Our starting point is to propose a framework that exploits the institutional details of the pipeline taking unlawfully present immigrants arrested by local law enforcement into ICE cus-

---

4See the policy memoranda issued by ICE’s director John Morton (Morton (2011a,b)).
tody, and subsequently into being deported. The immigration enforcement process effectively operates in a cascade fashion. After local law enforcement undertakes an arrest for any offense, government agents at the local and federal levels undertake efforts that may result in the arrestee’s transfer to federal custody. At that stage, the federal level, immigration courts and the immigrant (or his legal representation) jointly undertake efforts that determine whether he or she is removed from the US. Thus, observed removal rates depend on local and federal enforcement efforts, on how these interact along the immigration enforcement pipeline, and on the underlying composition of the pool of arrested unlawfully present individuals (because their characteristics may make them more or less favored by the local and federal levels). The key empirical challenge, thus, is to disentangle the roles of local and federal immigration enforcement efforts on the one hand, and of the composition of the arrest pool on the other, as drivers of the observed variation, across time and jurisdictions, in the observed removal rates. This is particularly difficult because local and federal enforcement choices are endogenous to each other (for example if the local level strategically responds to choices of the federal level), and are likely dependent on the characteristics of the arrest pool.

The pipeline nature of the Secure Communities program allows us to isolate enforcement choices from selection (unobserved characteristics of the pool of arrested unlawfully present individuals), and to isolate local from federal enforcement decisions. The automatic receipt of fingerprints by ICE after a local arrest implies that local-level enforcement choices have no (direct) effect on the likelihood of a detainer request, allowing us to isolate federal enforcement efforts from this first step. After ICE has issued a detainer request, the local level has full discretion to comply with it (by holding the arrestee until ICE picks him up) or not (by releasing the arrestee before ICE shows up), allowing us to isolate the local enforcement efforts from this second step. Tracing how the composition of the pool of arrestees is filtered through the several steps of the immigration enforcement pipeline, we are also able to disentangle the variation in the composition of the pool of arrestees from the variation in these enforcement choices. Leveraging these institutional features allows us to avoid imposing assumptions about details of the underlying game being played between the federal and the local levels, such as specific utility functions, beliefs, or information sets. We consider this to be a key methodological advantage of our approach. In fact, we begin with a fully non-parametric analysis under which we provide partial identification results. We then rely on mild parametric assumptions sufficient to point identify the parameters of interest and conduct the rest of the empirical analysis.

A parallel branch of federal immigration enforcement consists in the raiding of homes and workplaces by ICE. Because this branch of immigration enforcement does not involve the local level directly, we do not consider it here. For a discussion of the increasing use of ICE raids during the Bush administration, see Schmall (2009). During the Obama administration, however, ICE raids were a small component of all federal immigration enforcement activity: between 2009 and 2016, only 12 percent of removed individuals were in ICE custody as a result of a raid (our own estimate based on Freedom of Information Act requests to ICE).
We use detailed information on the universe of fingerprint matches under Secure Communities, the issuance of ICE detainers, the number of individuals under ICE custody, and the number of removals covering the period 2009-2014. We complement these data with information on a variety of county-level demographics. We first show that federal immigration enforcement did weaken considerably after the policy change, but that it cannot fully account for the pattern of changes in immigration enforcement outcomes along the deportation pipeline. In particular, strong selection forces in the composition of the pool of individuals facing prospects for removal, possibly endogenous to the changes in enforcement, were present. We also show that the choices of the local level had screening effects explaining part of these selection patterns.

We then estimate our model of the immigration enforcement pipeline under Secure Communities, and find most counties exhibit strategic substitutabilities in their response to federal enforcement efforts. This is true for cases of individuals accused of both minor and serious crimes. We find that local responses, however, were heterogeneous: more democratic and less Hispanic counties were more eager to undo the federal enforcement efforts by weakening their collaboration with ICE. A 10-percentage-points higher democratic vote share is associated with 7 percent and 25 percent more negative slopes in the response of the average county to changes in federal enforcement efforts over minor and serious offenses cases. We also find that changes in the acuteness of conflict between local and federal levels was mostly driven by a change in the profile of immigration cases prioritized by ICE. While ICE did strengthen its enforcement efforts towards serious offenses cases following the guidelines change, which was partially undone by the local level response, even more important quantitatively was the concomitant change in ICE’s priorities over the types of immigration cases it faced. Our results also uncover a remarkable targeting ability by ICE: under Secure Communities, the agency was able to direct its enforcement efforts towards counties where it could expect more local collaboration. We also subject our model to several specification tests, all delivering encouraging results.

Finally, we use our estimates to simulate the evolution of immigration enforcement outcomes under a counterfactual scenario where the federal enforcement guidelines were never modified, while holding the composition of the arrest pool constant. This allows us to quantify the importance of the endogenous response of the local level, with its consequent screening effects along the enforcement pipeline. In this scenario, among the set of relatively urban counties with high shares of immigrants for which we estimate our model, counterfactual deportations would have been 8.6 percent higher for minor offenses cases, and 41 percent higher for serious offenses cases than under the policy change. Around 60 percent of counties would have observed higher counterfactual deportations. Our results highlight how conflict over policy across vertical jurisdictional levels constitutes a first-order driver of policy-outcome heterogeneity. They also suggest that the implementation of enforcement technologies that become too effective may lead to reactive responses when there is conflict over the outcomes of such enforcement. Secure
Communities is a case in point, as its effectiveness in detecting unlawfully present immigrants required a large countervailing response by localities opposed to harsh immigration enforcement, and eventually led to the official demise of the policy itself.

Our paper contributes to the economics literature studying the effects of policy changes and interventions. A first concern—emphasized by Rosenzweig and Wolpin (1986) in the context of family planning subsidies—is related to the presence of spatial heterogeneity that may be correlated with the take-up or the intensity of the policy in question (see also Lalive and Zweimüller (2004); Meyer (1995)). Time-varying heterogeneity in the effects of policies is also a concern, even when using jurisdiction-level fixed effects (Besley and Case (2000)). In our context, the response of the local level to the federal level is a main source of heterogeneity in both the intensity of enforcement, and the effects of the policy (complementarities or substitutabilities between federal and local enforcement margins in the determination of the outcomes of interest may be present). By studying an institutional environment with features of federalism and policy overlap across levels of government, our methodological contribution is to address these concerns by leveraging the details of the institutional setting.

Within the literature on federalism and decentralization (Inman and Rubinfeld (1997a); Lockwood (2002); Strumpf and Oberholzer-Gee (2002)) we point to the local-federal alignment in preferences as a key political economy consideration for understanding variation in policy choice and policy outcomes. To the best of our knowledge ours is the first study recovering the enforcement responses of the local level to changes in federal-level enforcement. Because all interior enforcement of immigration in the US relies on the contact of unlawfully present immigrants with law enforcement, we also build on and contribute to the literature on the economics of crime and immigration. This literature has pointed out that toughened immigration enforcement drives immigrants towards illegal activities (Freedman et al. (2018)). Looking specifically at Secure Communities, however, both Miles and Cox (2014) and Treyger et al. (2014) find no effects of the program on crime rates. We show that differences in immigration enforcement preferences over immigrants with different criminal offense accusations are an important driver of the conflict between the federal and the local levels.

We also contribute to the literature on the political economy of immigration policy and law enforcement. Scholars have studied the correlates of local and state-level immigration legislation (Boushey and Luedtke (2011); Steil and Vasi (2014)). Their findings suggest that the presence of a large immigrant community and of Hispanics correlates strongly with the passage of ordinances weakening immigration enforcement. The ethnic identity of local law

---

6 A recent related literature studies how immigrants and their families alter their economic choices in response to increased immigration enforcement, for example in school attendance (Dee and Murphy (2018)), geographic mobility (Amuedo-Dorantes et al. (2013)), or social welfare program enrollment and take-up (Alsan and Yang (2018); Watson (2014)). Most of this literature suggests these behavioral responses are the result of “chilling effects”, as immigrants perceive interaction with government officials more risky.
enforcement is also correlated with the willingness to enforce immigration policies (Lewis et al. (2013)). Republican support, in contrast, is correlated with the adoption of stronger immigration enforcement policies, particularly in communities experiencing fast growth of the immigrant population (Ramakrishnan and Gulasekaram (2013)). Using a regression discontinuity design, however, Thompson (2018) finds no evidence of differences in compliance with detainer requests between barely elected Democratic or Republican sheriffs. In contrast, we find that local responses undoing federal efforts are stronger in more Democratic counties, but weaker where the Hispanic population share is larger.

Finally, a small literature has proposed modeling preferences over law enforcement to rationalize the observed patterns of policing and crime (Davila et al. (1999); Fu and Wolpin (2018); García-Jimeno (2016); Imrohoroglu et al. (2000)). Here we emphasize the importance of preference alignment when enforcement can be influenced by federal and local levels, and establish which are the most relevant county-level drivers of preferences over enforcement.

The remainder of this paper proceeds as follows. In section 2 we discuss immigration policy in the US, with a focus on the Secure Communities program. We introduce and describe the data in section 3. Based on our background discussion and on the main patterns in the data, section 4 develops a model of the immigration enforcement pipeline, and section 5 discusses identification and estimation. In section 6 we then present our main results and discuss their implications. Finally section 7 concludes. We present proofs and additional tables, figures, and data description in the online appendices.

2 Immigration Policy under Secure Communities

Starting with the 1849 Supreme Court decisions in Smith v. Turner and Norris v. Boston, the so called Passenger Cases, immigration policy and its enforcement in the US was gradually centralized. There the court established that levying state taxes on ships of immigrant passengers violated Article 1 of the Constitution. The Immigration Act of 1882, the first national-level piece of immigration legislation in the US, then allocated all power in determining the excludability and deportability of aliens to the federal level. However, it also left most practical enforcement to state-level officials (Hirot (2013); Hutchinson (2016)). Congress passed an additional piece of legislation in 1891 that completed the nationalization of immigration enforcement. This law granted wide discretion to immigration officers regarding admission of immigrants, raising early concerns about due process that reemerged recently under the Secure Communities program.

States and localities only began regaining a significant role in immigration policy with the 1986 and 1996 legislative overhauls of immigration law. Both acknowledged the potential for local involvement in immigration enforcement. The Immigration Reform and Control Act (IRCA) of 1986 legalized almost three million unlawfully present immigrants but introduced
employment restrictions for new ones. It also created the *Criminal Alien Program* (CAP), still in operation. Under CAP, local officials in prisons, jails, and courthouses share lists of inmates and allow ICE to perform interviews, after which ICE may issue detainer requests.\(^7\) The Illegal Immigration Reform and Immigrant Responsibility Act (IIRIRA) of 1996, in turn, allowed states and localities to participate in immigration enforcement. Section 287(g) of the law allowed for cooperation agreements with the federal government, whereby local law enforcement officials received training and authority to enforce federal immigration law.\(^8\)

Beyond these agreements, several states made further attempts at direct immigration enforcement. In 1993 California passed legislation mandating cooperation between state prisons and federal immigration authorities. California voters then approved Proposition 187 in 1994, requiring that state officials report suspected unlawful presence to federal authorities (*Gulasekaram and Ramakrishnan (2015)*)). This proposition was struck down by the courts, but it did trigger similar efforts in Arizona, Florida, and Texas.

### 2.1 The Secure Communities Program

Conflict over immigration policy has grown considerably in the 21st century, as local, state, and federal levels have all attempted to exert increasing influence over immigration enforcement. This may have been driven by the rising numbers of unlawfully present immigrants—from around 3 million in 1990 to about 12 million in 2008—, increased political polarization and partisanship, or the drastic changes in the structure of employment in the US economy.\(^9\) Variation across space in local preferences over immigration policy has grown, leading to sharp contrasts and reversals in the alignment of preferences between the federal and local levels.

States like Arizona led the charge on anti-immigration legislation. This state’s SB 1070 bill, passed in 2010, became a prominent piece of legislation empowering local law enforcement to participate in immigration enforcement. Colorado, Alabama, Georgia, and South Carolina undertook similar ‘copycat’ attempts (*Gulasekaram and Ramakrishnan (2015)*)). On the opposite extreme, several cities and counties have approved “sanctuary” ordinances requiring their law enforcement officials not to collaborate with federal officials, and to explicitly ignore immigration violations. Sanctuary legislation is not new—some cities passed similar ordinances in the

\(^7\) Through CAP, ICE has presence in every state and federal prison, and in more than 300 local jails. Currently CAP accounts for around half of all individuals taken into ICE custody (*Guttin (2010); Kalhan (2013)*).

\(^8\) This included the authority to screen individuals for their immigration status, investigate cases, issue detainers, arrest and issue charges for immigration violations, and access DHS’s databases. Approximately three percent of counties eventually entered into a 287(g) agreement, most of them after the 9/11 terrorist attacks. As of 2018, 78 such agreements are in place (see: [https://www.ice.gov/287g](https://www.ice.gov/287g)).

\(^9\) Using regression analysis for the US, both *Gulasekaram and Ramakrishnan (2015)* and *Steil and Vasi (2014)* find that the partisan share of the electorate is a robust predictor of local immigration legislation adoption in this period. *Fasani (2009)* finds in the Italian context that increases in labor demand led to significant falls in deportations of immigrants between 1994 and 2004 and suggests a political economy mechanism for this effect.
70s-90s-. In recent years, however, new forms of non-cooperation emerged, partly as a response to federal enforcement efforts under the Bush and Obama administrations.

Possibly the most prominent federal effort in immigration enforcement in this period is the Secure Communities program, the main focus of our attention in this paper. The program oversaw the largest expansion of local immigration enforcement in U.S. history (Kalhan (2013)). Participation in Secure Communities is mandatory. Its rollout began in 2008, but the program was officially discontinued in November 2014 after significant controversy and local and state resistance. However, the Priority Enforcement Program (PEP), a program in the same spirit and relying on the same institutional structure, replaced Secure Communities. Despite its demise, Secure Communities constituted a radical innovation, on both the institutional and the technological fronts. We now go on to describe how the program operated.

2.1.1 First Step: The Federal Level

Secure Communities restricted significantly the ability of local police to exercise discretion over immigration enforcement. Under standard procedure following a local law enforcement arrest for any reason, the arrestee’s fingerprints are scanned and checked against the FBI’s identification and criminal records database (IAFIS) during booking. Under Secure Communities, upon receipt of these fingerprints, the FBI directly and automatically transmits them to the DHS for comparison against its Automated Biometric Identification System (IDENT). If there is a

---

10ICE designed Secure Communities in response to a 2008 Congressional directive to “identify every criminal alien, at the prison, jail, or correctional institution in which they are held.” (see Consolidated Appropriations Act of 2008).

11In the memorandum officially ending the Secure Communities program, the Secretary of Homeland Security Jeh Johnson argued that “The goal of Secure Communities was to more effectively identify and facilitate the removal of criminal aliens. But the reality is the program has attracted a great deal of criticism, is widely misunderstood, and is embroiled in litigation; its very name has become a symbol for general hostility toward the enforcement of our immigration laws. Governors, mayors, and state and local law enforcement officials around the country have increasingly refused to cooperate with the program, and many have issued executive orders or signed laws prohibiting such cooperation” (see Johnson (2014)).

12The Trump administration subsequently re-labeled PEP as Secure Communities.

13IDENT currently holds around 150 million records, and grows at around 10 million new entries per year. It contains information of any individual who has had contact with DHS, including visa applicants in other countries, non-citizens traveling through the US, non-citizens applying for asylum or other benefits, unlawfully present immigrants apprehended at the border, anyone participating in ‘trusted traveler’ programs, parents who have adopted children abroad, naturalized citizens, and anybody whose fingerprints have been collected through Secure Communities. It aggregates information from ICE, the Customs Border Protection, the US Coast Guard, the US Citizenship and Immigration Services, the Department of State, the Department of Defense, the Department of Justice (including all FBI databases), Interpol, the Five Country Conference (an information sharing agreement between the US, the UK, Australia, Canada and New Zealand), and the Preventing and Combating Serious Crime international agreement (see Privacy Office, US Department of Homeland Security, Privacy Impact Assessment for the Automated Biometric Identification System (IDENT) 1115 (2012), Office of Inspector General, US Department of Homeland Security, Operations of United States Immigration and Customs Enforcement's Secure Communities 45 (2012), and DHS, Privacy Impact Assessment for the Automated Biometric Identification System (2012)).
Figure 1: Number of Detainers and removals, 2003-2015. Figure (a) shows the aggregate number of detainers issued (red) and removals (blue) for arrestees charged with minor (levels 2 and 3) offenses. Figure (b) shows the aggregate number of detainers issued (red) and removals (blue) for arrestees charged with serious (level 1) offenses. Data are aggregated at the quarterly level. Source: TRAC.

match to an unlawfully present individual, or even if there is no match but the individual has no known place of birth, the system automatically flags the record and notifies ICE. ICE itself then undertakes further checks on its own and other databases, and informs the corresponding ICE field office about any relevant findings. The field office then decides whether or not to submit a detainer request to the local jail where the arrestee is being held. In this way, under Secure Communities immigration status verification became routine part of law enforcement. As a crucial first feature of the program, it effectively eliminated all local-level discretion over immigration status verification: the local level can no longer affect the likelihood that the federal level learns about the immigration status of an arrestee. This is in sharp contrast to the ample local discretion possible under CAP or 287(g).

Once ICE officials have identified a person of interest being held at a local detention facility, they must decide whether or not to issue a detainer. Detainers are addressed to the local law enforcement agency, requesting to hold the arrestee in custody for up to an additional 48 hours. This gives ICE officers time to take the arrestee into custody. The detainer issuance decision is complex. ICE officials must evaluate all the information they have (and do not have) about the

---

14 ICE is organized geographically into 24 federal enforcement districts (see Figure B.2).
15 Facing some challenges to this aspect of the policy (e.g., Santos v. Frederick County Board of Commissioners (2013), Doe v. Immigration and Customs Enforcement (2006)), DHS explicitly makes it clear that “a jurisdiction cannot choose to have the fingerprints it submits to the federal government processed only for criminal history checks” because “the sharing [of fingerprints] was ultimately between the FBI and DHS” (see Kalhan (2013)).
16 The only possibility here would be for the officers to not collect the fingerprints of an arrestee they believe may be illegally present in the country. This would constitute malpractice and would not allow the police to establish the criminal status of the individual in custody, making it impractical (Gulasekaram and Ramakrishnan (2015)). On the other hand, the arresting behavior of the police may have changed in response to the introduction of Secure Communities, which constitutes a first order source of selection which we will deal with below.
arrestee. This includes the severity of the offenses charged and any other prior criminal history, the individual’s likelihood of being removed once under federal custody, and the availability of resources required to deploy a team that picks up the individual in the local detention facility. ICE officers follow a series of priority guidelines issued by ICE directors. They are also likely to have strategic considerations in mind: issuing a detainer request effectively ‘alerts’ the local level of the federal level’s interest in the arrestee. If ICE officers deem the locality immigrant friendly, they may expect local law enforcement to expedite the release of the arrestee in response to the detainer. Federal discretion over the issuance of detainer requests is the second key feature of the institutional design of the program.

The main source of variation we exploit is the drastic change in the official priority guidelines for prosecutorial discretion undertaken by the Obama administration in the summer of 2011. The first two years of the Obama administration continued a trend of strengthened federal immigration enforcement, with increasing numbers of detainer requests and removals across the US. Increased federal enforcement led to pressure from local governments and immigration advocacy groups, which, together with the forthcoming presidential election, were key factors explaining the policy change. Figure 1 plots the aggregate trends in the number of detainers and removals by offense severity (see below), showing the striking reversal around mid 2011. The new policy guidelines, outlined in a series of memos by ICE director John Morton, were predicated upon refocusing federal efforts and resources away from the prosecution of unlawfully present immigrants accused of minor offenses or just immigration violations, and towards those accused of serious crimes. According to Morton,

“ICE must prioritize the use of its enforcement personnel, detention space, and removal assets to ensure... the agency’s enforcement priorities, namely the promotion of national security, border security, public safety, and the integrity of the immigration system... Because the agency is confronted with more administrative violations than its resources can address, the agency must regularly exercise ‘prosecutorial discretion’,... the authority of an agency charged with enforcing the law to decide to what degree to enforce the law against a particular individual” (Morton (2011a)).

The memo goes on to specify which ICE officers are allowed to exercise discretion, and a long list of criteria for them to follow. Additional memos provided further instructions on the subject (Morton (2011b)). In practice, the Secure Communities program used a four-level classification for offenses. Level 1 being the most serious, includes convictions for homicide, kidnappings, sexual assault, and terrorist activity among others. Levels 2 and 3 include convictions for less serious crimes such as burglary, theft, traffic offenses, small drug offenses, and immigration violations (for the full list of categories of offenses, see ICE (2008)). Level 4 includes individuals

17Compared to the pre-program period, Secure Communities saw a tenfold increase in the number of detainers issued by ICE (Kalhan (2013)).
that have not been yet convicted. The new guidelines redirected federal enforcement towards level 1 offenses. Our empirical strategy below will rely on this distinction.

2.1.2 Second Step: The Local Level

Local law enforcement is able to exercise discretion over immigration outcomes as well, but in the next stage of the process. Once ICE has submitted a detainer request, local law enforcement is free to decide whether to ‘honor’ it by holding the arrestee until pick up by ICE, or not to honor it by either releasing the arrestee before ICE shows up, or by refusing to hand over the immigrant to ICE. Indeed, detainer requests are not binding for the local level, and constitute only suggestions of collaboration.\textsuperscript{18} Thus, the third key feature of Secure Communities is the complete discretion of the local level after a detainer has been issued.

This is also the stage at which the extent of preference alignment between the local and the federal levels is made manifest: because ICE moves first when deciding whether to issue a detainer or not, any arrestee for whom a detainer is issued is necessarily highly desired by the federal level, irrespective of ICE officers’ beliefs about how the local level may react. This need not be the case for arrestees for whom ICE abstains from issuing a detainer; this set will include all arrestees ICE is uninterested in, and other arrestees which are of interest but for whom the agency did not issue a detainer based on strategic considerations. If the preferences of the local level are aligned with those of the federal level, local officials will be likely to honor the detainer request. Otherwise (i.e., the characteristics of the arrestee are such that the local level would rather not see this arrestee under ICE custody), we may expect the local officials not to honor the detainer. As a result, the rate of compliance with detainer requests will be informative about the extent of alignment of preferences between the local and federal levels.

Variation in local cooperation is partly driven by local preferences over the presence of unlawfully present immigrants. It also depends on the costs of compliance. First, holding arrestees for longer is expensive, and diverts resources from law enforcement. Moreover, localities also expressed concern about how participation in immigration enforcement would erode community trust. Indeed, conflict over Secure Communities grew rapidly as the federal government rolled it across the US. Several advocacy groups such as the National Day Laborers Network organized a resistance movement, focused on crafting legislation and lobbying local governments. In its non-cooperation ordinance, for example, the Cook county, IL council argued:

\textsuperscript{18}This has been established by several appeals and state supreme court rulings affirming the right of local level agencies to exercise discretion at this point under the anti-commandeering doctrine founded on the Tenth Amendment (See Galarza v. Szalczyk (2014), Jimenez-Moreno et al. v. Napolitano et al. (2014), Buquer v. City of Indianapolis (2011), or Printz v. United States (1997) among others). ICE officials themselves have acknowledged that detainers constitute only a collaboration suggestion. Moreover, some counties have argued that holding an arrestee who has not otherwise been charged with a crime, in response to a detainer request, may constitute a due process violation (Manuel (2012); Pham (2006)).
“... it costs Cook county approximately $43,000 per day to hold individuals... pursuant to ICE detainers, and Cook county can no longer afford to expend taxpayer funds to incarcerate individuals who are otherwise entitled to their freedom... having the sheriff... participate in the enforcement of ICE detainers places a great strain on our communities by eroding the public trust the sheriff depends on to secure the accurate reporting of criminal activity...” (Cook county board of commissioners, Sept. 7, 2011)

Most of this legislation has the purpose of limiting the extent to which the local level collaborates in honoring ICE detainers. Some of the ordinances and regulations instruct local police to honor only detainers for arrestees charged with serious crimes. The best known example is California’s TRUST Act, passed in 2013.19

2.1.3 Third Step: ICE Custody and Removal

Arrestees in local detention facilities are taken into ICE custody in two ways. They may be picked up by ICE officers pursuant to a detainer request, which we refer to as the ‘detainer track’. Or they may be picked up by ICE officers who show up to a local jail or prison unannounced in search for unlawfully present individuals. We refer to this as the ‘direct track’. A key distinction between both tracks is that for arrestees with an issued detainer, the local level’s detainer compliance decision fully determines the likelihood they are taken into ICE custody. For arrestees for whom no detainer was issued, both federal and local efforts shape the likelihood they are taken into ICE custody.20 This distinction and availability of data from both tracks will be crucial for the identification strategy we lay down below.

In either case, individuals under ICE custody go on to a deportation proceeding involving immigration court. Under US law, immigration courts are not part of the judicial branch. Rather, they constitute a division within the Department of Justice, and thus, are part of the federal executive branch. As such, we may expect the outcomes at the removal stage to be correlated with the patterns of federal immigration enforcement earlier in the process, even though immigration courts are expected to apply the law uniformly and to respect due process and fair treatment. Unlawfully present individuals under ICE custody are free to waive their right to an immigration proceeding, in which case they are directly removed.21

20This will depend on the implicit or explicit negotiation between local and federal law enforcement at the time when ICE officers show up in a local detention facility.

21A host of legal aid organizations provide council to those who do not waive their right and are unable to hire private counsel. Although technically possible, the IIRIRA restricted considerably the possibility of appeals in the immigration court system, as it strips the federal courts of jurisdiction to hear legal challenges to deportation decisions (Zolberg (2006)).
3 Data Description

The Immigration Enforcement Pipeline. Our data on the immigration enforcement pipeline comes from two main sources. First, a series of Freedom of Information Act (FOIA) requests to DHS, from which we obtained information from the Secure Communities program at the county level, covering the universe of cases of unlawfully present individuals moving along the immigration enforcement pipeline between October 2008 and February 2015. These detailed data include the number of fingerprint submissions from local detention facilities with matches to the DHS’s IDENT database, the number of detainers issued by ICE, the number of individuals in ICE custody, the number of removals, and the ICE level of priority based on crime severity. For our purposes, we will consider level 1 as serious crimes, and levels 2 and above as minor crimes. We use the number of fingerprint matches as our measure of local arrests of unlawfully present individuals. Second, we collected data from the Transactional Records Access Clearinghouse (TRAC) at Syracuse University. Based on several FOIA requests, TRAC has built updated record-by-record datasets of detainers, removals and Secure Communities removals with information from 2002 to the present. All datasets have information on the most serious crime conviction, priority level for ICE, country of birth, age, and sex of the immigrant. We combine these two sources and aggregate the data at the county-semester level, beginning with each county’s enrollment in the program. We reconstruct measures by crime severity (serious and minor) of counts of arrests of unlawfully present individuals, detainers issued by ICE, individuals entered into ICE custody with and without a detainer request, and removed individuals under ICE custody with and without a detainer request.

Table B.1 presents descriptive statistics at the county-semester level for the several stages of the immigration enforcement pipeline. It reports counts of events, and divides the data between the pre and post policy guidelines change. The number of observations in the pre-guidelines regime is smaller than in the post-guidelines regime for two reasons: first, the pre period covers five semesters, while the post period covers seven semesters. Second, enrollment into the Secure Communities program, albeit mandatory for the counties, happened gradually as ICE rolled out the program starting in October 2008. By January 2013 all US counties were enrolled, and

---

22 Naturally, false positives can arise when ICE flags a US citizen by mistake. Similarly, false negatives can arise when ICE fails to flag an unlawfully present immigrant. The former are likely to establish their citizenship later, and the latter will not be subject of ICE prosecution so these cases will introduce little error on our counts of detainers, custodies, and removals. On the other hand, fingerprints from an arrestee may be submitted multiple times. We have no reason to believe such occurrences may be related to immigration enforcement concerns, and were unable to identify any such cases from these data.

23 The TRAC dataset allows us to assign the detainer requests to counties, and to establish whether a given removal followed a detainer request or not. Most importantly, this dataset allows us to assign ICE custody and removals cases to the detainer and the direct tracks (the data from DHS does not contain this information). We do the assignment by applying the TRAC-based shares of individuals under ICE custody or removed with detainers to the FOIA-based counts. Overall both sources agree, although we need to undertake some adjustments (described in Appendix C) in a subset of cases where inconsistencies arise.
by the time of the policy change in June 2011, more than 70 percent of the US population was living in counties enrolled in the program (see Figure B.1 in Appendix B). Naturally, the timing of enrollment into Secure Communities is correlated with key county characteristics. Particularly predictive is the share of Hispanics (see Cox and Miles (2013)). Indeed, DHS possibly targeted counties for enrollment as a function of its own objectives, so entry into the sample is an important source of selection that may be reflected in these tables.24

Throughout this paper we restrict attention to counties with an estimated share of undocumented immigrants above median (1 percent of the population), and thus, where there can be some federal-local conflict over immigration. Elsewhere immigration enforcement is not a locally salient issue, and we observe no variation in immigration outcomes.25

**County Characteristics.** We collected an array of county-level characteristics related to local preferences over immigration enforcement. We report summary statistics for these variables in Panel A of Table B.2. To capture political preferences, we focus on the Democratic share of votes from the 2008 and 2012 presidential elections, using David Leip’s atlas of US presidential elections.26 We also use other demographic characteristics taken from the American Community Survey 2006-2010 waves, as sources of variation in preferences over immigration enforcement: population, Hispanic share, share of adults with a bachelors degree, and share of employment in the services sector. Finally, Table B.2 reports summary statistics for whether the county is considered rural, the county’s distance to its corresponding ICE district headquarters (see Figure B.2), and for the presence of 287(g) agreements (see Mayda (2006), for a discussion of the correlates of preferences over immigration policy).

### 3.1 Patterns of Immigration Enforcement Outcomes

We now present descriptive results illustrating the main changes in the patterns of immigration enforcement outcomes at each step along the immigration enforcement pipeline following the 2011 guidelines. Together, these results motivate our subsequent empirical strategy and mod-

---

24Neither Cox and Miles (2013) nor we find the county-level Democratic share to be predictive of Secure Communities activation after controlling for the Hispanic share.

25We construct a measure of the undocumented share using: the share of Hispanic non-citizens from the 2010 census, the number of tax returns filed without a social security number from Brookings (see https://www.brookings.edu/interactives/earned-income-tax-credit-eitc-interactive-and-resources/), and state-level estimates of unlawfully present population from Warren and Warren (2012). See Appendix C for a detailed explanation.

26See www.uselectionatlas.org. Besides the well established county-level correlations between local immigration enforcement regulations and Republican vote share, this relationship holds as well at the individual level: the 2015 American Trends Panel survey from the Pew Research Center, for example, found 71 percent of Republican voters believe that immigrants in the US make crime worse, compared to 34 percent of Democratic voters. See http://www.pewresearch.org/fact-tank/2015/09/30/on-views-of-immigrants-americans-largely-split-along-party-lines/.
eling approach. To do this in a flexible way, we focus on measuring the average slope of the relationship between the outcome of a given step along the pipeline, \( y_{ct} \), and its corresponding baseline, \( B_{ct} \). For example, in the first step of the detainer track, we are interested in how many detainer requests are issued per unlawfully present immigrant in police custody. Estimating a fixed effects model, we recover the average rate at which baseline events translate into outcome events, and any differences in this rate between the pre and post-policy guidelines periods:

\[
y_{ct} = \alpha_c + \alpha_t + \beta B_{ct} + \gamma(B_{ct} \times \text{Guidelines}_t) + \mathbf{x}'_{ct} \eta + \epsilon_{ct}
\]

where \( y_{ct} \) is an immigration enforcement outcome (detainers, ICE custodies, removals), \( B_{ct} \) is its corresponding baseline variable along the pipeline (arrests in the case of detainers, detainers in the case of ICE custodies, ICE custodies in the case of removals) and \( \mathbf{x}_{ct} \) is a vector of controls.\(^{27}\)

Periods when the baseline variable is zero do not contain information on the enforcement rate, so the estimating samples only include observations for which \( B_{ct} > 0 \).

We estimate \( \gamma \) for the different steps of the deportation process. We use a standard inverse hyperbolic sine transform over the \( y_{ct} \) and \( B_{ct} \) counts, so the coefficients can be interpreted approximately as elasticities. Notice, however, that these coefficients do not have a causal interpretation: they will reflect equilibrium changes in enforcement by federal and/or local levels in response to the change in the guidelines, as well as equilibrium changes in the composition of the pool of baseline cases along dimensions relevant for enforcement decisions. This heterogeneity represents characteristics of the arrestees over which the local and federal levels have conflicting preferences regarding deportation. The pool of arrestees can change endogenously for several reasons. First, secular demographic patterns, such as the steady growth of the Central American migrant population in this period, can impact the composition of the pool of arrestees. Second, keeping constant the composition of the pool of immigrants arrested, federal and local preferences over the deportability of different types of immigrants may change. For example, under the 2011 guidelines ICE prioritized for removal immigrants without American-born children. Third, immigration enforcement itself can alter the composition of the pool of arrestees: it can undermine community collaboration with law enforcement relevant for efficient policing, and it can shift the supply of crime through both deterrence and incapacitation.\(^{28}\) Moreover, each step of the immigration enforcement pipeline will generate

\(^{27}\)\( \mathbf{x}_{ct} \) includes log population, and interactions between semester dummies and each of the following time-invariant characteristics: state dummies, ICE federal district dummies, undocumented share of the population, Hispanic share of the population, Democratic party share of the presidential vote, share of the population with a bachelors degree, a dummy for rural counties, and log distance to the corresponding ICE district headquarters.

\(^{28}\)For example, suppose the guidelines led to weakened local immigration enforcement, and that this improves policing efficiency, leading to higher apprehension rates for minor offenses. The pool of arrestees will become selected towards these kinds of offenses, which are on average less likely to be requested by ICE. Thus, in the regression of detainers on arrests, \( \gamma \) will be negative partly as a result of weakened enforcement, and partly because the pool of arrestees endogenously shifted toward people over which ICE has little interest.

Table 1: County Fixed Effects Models for the Steps of the Immigration Enforcement Process The table shows regression coefficients for panel fixed effects models for the different steps of the immigration enforcement process by type of arrest according to ICE’s classification. All models include county fixed effects, semester fixed effects, log population, and interactions of semester fixed effects with the following time-invariant covariates: state dummies, federal enforcement district dummies, undocumented share of the population, Hispanic share of the population, Democratic party share, share of the population with a bachelors degree, a dummy for rural counties, and log distance to the corresponding ICE district office. Panel A presents results for the detainer track, while Panel B presents results for the direct track. Arrests correspond to the number of fingerprint matches under Secure Communities. Custodies and Removals in Panel A correspond to those for which a detainer was issued. Custodies and Removals in Panel B correspond to those for which no detainer was issued. Guidelines is a dummy variable indicating the semesters after the policy guidelines change under the Obama administration. All models exclude observations for which the baseline regressor is zero. Standard errors are robust to arbitrary heteroskedasticity, and clustered at the county level.
selection in the downstream steps. This is especially clear when, for example, changes in the
arrests-to-detainers stage lead to zero detainers, so that we no longer have information about
enforcement rates in the detainers-to-custodies stage.

**Minor Offenses.** Along the detainer track, column 1 in panel A of Table 1 shows a significant
coefficient on the interaction term: in the post-guidelines period, the rate at which arrests for
minor offenses translate into detainer requests for the average county falls by more than 10
percent \((-0.066 \text{ (s.e. } = 0.017)\) relative to a baseline of 0.614 (s.e. = 0.028)). This quantitatively
large fall suggests that ICE did comply with the policy guidelines, by weakening enforcement
towards minor crimes through the channel of reduced numbers of detainer requests. In the
post-guidelines period, detainers also translate into ICE custodies at a smaller rate on average
\((-0.046, \text{ s.e. } = 0.025\) relative to a baseline of 0.64, s.e. = 0.03), although this difference is
significant at the ten percent level only. This fall may be masking heterogeneous responses
to the federal enforcement change, across counties with different preferences. It may also be
driven by a significant change in the pool of unlawfully present individuals: although these are
people detained for minor offenses, the federal level may already have screened out the least
severe of these offenses when reducing the issuance of detainers.

Column 3 then moves towards the last step of the pipeline, where immigration courts with
perhaps some influence by ICE determine the rate at which individuals in ICE custody are
removed. This rate is no different between the pre and the post-guidelines periods. On the one
hand, the immigration courts may have weakened their enforcement standards as well. On the
other, the pool reaching an immigration court proceeding in the post-guidelines period may be
composed of individuals with characteristics more favorable to deportation. As a complement
to these results, column 4 reports the compounded effects implied by the full detainer track,
looking at changes in the rate at which arrests of unlawfully present immigrants translate
into final removals. Removals per arrest are indistinguishable between pre and post-guideline
change periods for the average county. Considering how quantitatively large the federal policy
change was, this suggests strong selection forces at play over the pool of people being taken
through the immigration enforcement pipeline. Indeed, significant differences in the rates at
which unlawfully present immigrants move along the first two steps of the pipeline following
the change in guidelines can only be consistent with no differences in the net rate of removals
if a large change in the composition of the pool of arrestees took place simultaneously.

Columns 1 and 2 in panel B report analogous results for the direct track, still among minor
offenses cases. Along this track, the post-guidelines change period also saw a large and precisely
estimated fall in the rate at which arrests translate into ICE custodies \((-0.09, \text{ s.e. } = 0.02)\). This
fall is proportionally larger than the one observed along the detainer track.
Serious Offenses. In columns 5-8 of panel A we present the main patterns on immigration cases tagged as serious offenses. The 2011 policy guidelines advocated a shift towards immigration enforcement of serious offenses cases. Column 5 reports a statistically insignificant coefficient on the differential rate at which local arrests translate into ICE detainer requests (0.029, s.e.= 0.022). The fall in the raw numbers of detainers issued by ICE illustrated in Figure 1 above makes this finding particularly striking. It suggests a concomitant fall in arrests of unlawfully present immigrants, leading to large changes in the composition of this pool.

In the post-guidelines period detainers translate into ICE custodies at a lower rates (see column 6). In contrast, we observe a large post-guidelines increase of around 50 percent in the conditional removal rate at the ICE custody stage (in column 7, the interaction term is 0.136, s.e.= 0.039 compared to a baseline coefficient of 0.287, s.e.= 0.046). A similarly large change at the ICE custody stage can be seen along the direct track. In column 3 of panel B we show that along this track, on average each arrest led to less ICE custodies after the guidelines were issued, but to more removals in the post-guidelines period. Part of this pattern may be driven by a strongly selected pool of arrestees with characteristics highly amenable to deportation, and part by increased enforcement across the board at the immigration court stage.

A comparison between the detainer and no detainer tracks for serious offenses also suggests an enforcement response from the local level. If federal enforcement behaved similarly along both tracks, then the lower rates at which detainers and arrests translate into ICE custodies suggest a resistance response by the local level to the shift in enforcement towards serious crimes. Moreover, the local level may have resisted the removal of the least serious among these cases. This has a screening effect, selecting the pool of those who reach the immigration court stage towards individuals the immigration courts are eager to remove. To distinguish between these different margins, below we directly model the immigration enforcement pipeline.

4 A Model of the Immigration Enforcement Pipeline

We now present a framework to disentangle the three key sources of variation in the patterns of immigration enforcement outcomes we described in section 3: local enforcement, federal enforcement, and selection in the composition of the pool of unlawfully present immigrants moving along the pipeline. It will allow us to track how arrested individuals are filtered along this pipeline, and to capture the key features we highlighted above as critical for our empirical strategy. Most importantly, by incorporating time-varying unobserved heterogeneity in the composition of the pool of arrested unlawfully present individuals, we directly capture any misalignment of preferences over removals between the federal and local levels. Our knowledge of the institutional details of the enforcement process allows us to abstain from taking stances over utility functions, beliefs, or other details of the implicit game between the federal and local
levels, and to remain almost fully non-parametric. Besides relying on the structure provided by the pipeline, we only rely on two substantial and readily interpretable assumptions made explicit below. Because the 2011 change in policy guidelines explicitly proposed directing federal enforcement efforts towards serious offenses cases, we condition the analysis on the (observed to us) crime severity, effectively allowing both the federal and the local levels to choose different intensities of immigration enforcement towards serious and minor offenses.

4.1 The Immigration Enforcement Process

Arrested unlawfully present immigrants vary in observed and unobserved (to us) characteristics. Conditional on their observed characteristics, most prominently the seriousness of the offense for which they were arrested, the local and federal levels may disagree on whether the individual
should be a high or low removal priority. Because the relevant conflict between local and federal
levels revolves around removal, the table at the top of Figure 2 describes the distribution of the
relevant unobserved heterogeneity in the pool of arrestees in a given county and time period.\(^{29}\)
\(\pi^{L\ell}\) is the fraction of arrestees who are low priority for ICE \((L)\) and low priority for the county
\((\ell)\), while \(\pi^{HH}\) is the fraction of arrestees who are high priority for both ICE \((H)\) and the county
\((h)\). The higher these fractions, the more aligned the preferences of both levels. In contrast, \(\pi^{Lh}\)
is the fraction of arrestees ICE is not interested in removing \((L)\), but the local level would prefer
were removed \((h)\). \(\pi^{H\ell}\) is the fraction of arrestees ICE would like to remove \((H)\), but the local
level would not want to see removed \((\ell)\). The higher these fractions, the more misaligned the
preferences of the federal and the local level. Our knowledge of the immigration enforcement
pipeline and its two “tracks” will allows us to trace how the pool of arrestees is filtered along
the process, and to separately recover federal and local immigration enforcement efforts.

4.1.1 The Detainer Track

Along the first track, the ICE district office is automatically informed about the arrest of
an unlawfully present individual, and decides whether to issue a detainer. Detainers are not
issued for type \(L\) arrestees: \(\mathbb{P}(\text{Detainer}|L) = 0\).\(^{30}\) For type \(H\) arrestees, ICE issues a detainer
with a probability that depends on the current intensity of federal immigration enforcement:
\(\mathbb{P}(\text{Detainer}|H) = f\). Conditional on observed characteristics, this probability is constant within
time periods (in our baseline empirical application, this will correspond to semesters). The 2011
guidelines, for example, directly changed \(f\).

**Assumption 1.** *ICE does not condition on the local level preference type \(\{h, \ell\}\).*

This is a weak assumption. First, recall it is conditional on the seriousness of the alleged
offense. Moreover, from the point of view of ICE, all \(H\) types are on average equally desirable
irrespective of their local type, \(h\) or \(\ell\). \(\{h, \ell\}\) are residual characteristics of the arrestee directly
relevant for the local level only. Part may represent characteristics of the arrestees that are
observed by the local level but unobserved by ICE agents. Naturally, ICE agents cannot
condition on these. Part, however, may be observed by ICE. Assumption 1 thus amounts to
ruling out commitment by ICE, at the stage in which it is informed about a person of interest
and must decide to act on this information. For example, forward-looking ICE agents might
to want make inter-temporal promises of lenient future behavior to obtain the sheriff’s present
collaboration over an individual they believe the local level may not want to remove. When
a new fingerprint match arrives, we believe it is unlikely that ICE agents will be able to keep

\(^{29}\)All variables refer to a given county-time period \((c, t)\). We omit those indices in this subsection as it does
not lead to any confusion.

\(^{30}\)Notice that this is not an assumption. It simply corresponds to the definition of an \(L\) type.
such a promise. This is particularly so because, on average, each ICE enforcement district is simultaneously responsible for more than a hundred different counties. Thus, we observe

$$P(D|A) = (\pi_{H\ell} + \pi_{Hh})f \equiv P_{D|A} \quad (2)$$

at the county×time period level. Equation (2) shows that $P_{D|A}$ varies over time either through changes in federal enforcement $f$, or through changes in the composition of the pool of arrestees.

After ICE has issued detainers, the resulting distribution of detainers can be represented by the second table on the left of Figure 2. This distribution does not depend on $f$ because the federal level does not select detainers based on local level preferences. It does not have $L$ types either, which the federal level has filtered out. Now county-level officials must decide whether to honor the detainer. The county is happy to hand in $Hh$ type arrestees: $P(ICE\ Custody|Detainer,Hh) = 1$. In contrast, there is conflict over $\ell$ types, which the county may not want to hand in. The county’s willingness to enforce immigration can be captured by the conditional probability of honoring such detainers: $P(ICE\ Custody|Detainer,H\ell) = g$. As such, the probability of observing detainers translate into ICE custodies is

$$P(ICE\ Custody|Detainer) = 1 \times \frac{\pi_{Hh}}{\pi_{H\ell} + \pi_{Hh}} + g \times \frac{\pi_{H\ell}}{\pi_{H\ell} + \pi_{Hh}} \equiv P_{C|D} \quad (3)$$

We also observe $P_{C|D}$ at the county×time period level. $P_{C|D}$ can vary over time because among $H$ types the pool of arrestees is shifting between $h$ and $\ell$ types, or because local immigration enforcement $g$ is changing, or both: changes in the rate at which detainers translate into ICE custodies may be driven by changes in local enforcement or selection. Crucially, the full discretion of the local level in honoring detainers provides us with an exclusion restriction: $P_{C|D}$ does not vary with federal immigration enforcement $f$.

Once in ICE custody, removal decisions depend on efforts made by ICE and the immigration courts. Every individual in custody is an $H$ type. Because ICE and the courts may have misaligned preferences, to be fully general we must allow court-stage removal rates to vary with the remaining source of unobserved heterogeneity, $j \in \{\ell, h\}$. We denote by $q_j = P(Removal|ICE\ Custody,Detainer,j)$ the conditional probability of removal of an $Hj$ type. Both of these conditional probabilities will in general be interior. They will depend on the intensity of federal enforcement, and on the preferences of the district courts. They will not, however, depend on local enforcement, which constitutes an additional exclusion restriction implied by the pipeline. We can express the conditional removal probability among people in ICE custody for whom a detainer was issued as

$$P(Removal|ICE\ Custody,Detainer) = q_{\ell} \frac{g_\pi H\ell}{g_\pi H\ell + \pi Hh} + q_h \frac{\pi_{Hh}}{g_\pi H\ell + \pi Hh} \equiv P_{R|C,D} \quad (4)$$
We also observe this conditional probability. It will vary with court and federal immigration enforcement (through \((q^\ell, q^h)\)), with local immigration enforcement (through \((\ell, h)\)), and with the distribution of types in the pool of arrestees. Equation (4) reveals an important pattern of selection induced by the structure of the immigration enforcement pipeline: if the courts’ preferences are strongly aligned with the county’s preferences \((q^h > q^\ell)\), then all else equal, a fall in local immigration enforcement, \(g\), will increase \(P_{R|C,D}\) even if the distribution of types and court and federal enforcement remain constant. The reason is a screening effect from local immigration enforcement over the pool of people in ICE custody: when the county reduces enforcement, the share of \(H^\ell\) individuals handed into ICE custody falls. The pool of custodies becomes selected towards \(H^h\) individuals, which courts are more willing to remove.

4.1.2 Partial Identification from the Detainer Track

Our analysis allowed us to relate three observable conditional probabilities, \((P_{D|A}, P_{C|D}, P_{R|C,D})\) to four enforcement intensity rates \((f, g, q^\ell, q^h)\) and the fraction of \(H^\ell\) and \(H^h\) types in the pool of arrested immigrants. We can conveniently re-express them in the following way:

\[
x_1 \equiv P_{D|A} = (\pi^{H\ell} + \pi^{Hh})f \tag{5}
\]
\[
x_2 \equiv P_{D|A}P_{C|D} = (g\pi^{H\ell} + \pi^{Hh})f \tag{6}
\]
\[
x_3 \equiv P_{D|A}P_{C|D}P_{R|C,D} = (q^\ell g\pi^{H\ell} + q^h \pi^{Hh})f \tag{7}
\]

Equations (5)-(7) provide us with two independent relationships between these observable probabilities and the unobservable enforcement rates: Taking the ratio of equations (5) and (6) for county-time periods with a positive number of ICE custodies,

\[
\frac{\pi^{Hh}}{\pi^{H\ell}} = \frac{x_2 - x_1 g}{x_1 - x_2}. \tag{8}
\]

Taking the ratio of (6) to (7) for county-time periods with a positive number of removals,

\[
\frac{\pi^{Hh}}{\pi^{H\ell}} = \frac{(x_3 - x_2 q^\ell)g}{x_2 q^h - x_3}. \tag{9}
\]

Equating these ratios we obtain the following relationship between \((g, q^\ell, q^h)\) and observables:

\[
g = \frac{x_3 - x_2 q^h}{x_3 - x_2 q^\ell - x_1(q^h - q^\ell)}. \tag{10}
\]

Crucially, this relationship does not depend on the composition of the pool of arrestees \((\pi^{Hh}, \pi^{H\ell})\). By exploiting the variation across steps of the immigration enforcement pipeline along the de-
tainer track, we obtain a relationship between local and court-enforcement probabilities that is purged of any selection issues. This is convenient because \((\pi^Hh, \pi^H\ell)\) is unobserved and can be correlated with the enforcement choices at all the different stages. The manifold described by equation (10) provides a partial identification set for the three enforcement probabilities, provided that \(x_1, x_2, x_3 > 0\). Finally, notice also that the ratio \(\pi^Hh / \pi^H\ell\) is a measure of the extent of preference alignment between the federal and the local levels. From equation (8), if we can recover \(g\), we will also have recovered the preference alignment ratio non-parametrically.

4.1.3 The Direct Track

Parallel to the issuance of detainers under Secure Communities, ICE also visits jails and prisons directly attempting to bring unlawfully present immigrants into custody. The Criminal Alien Program (CAP) is one of the main enforcement vehicles through which these efforts are implemented. Resource and political economy constraints limit the extent to which ICE issues detainers towards \(H\) types. Under Secure Communities, after ICE is informed of a fingerprint match and decides not to issue a detainer, it may subsequently employ the ‘direct track’ over the corresponding arrested immigrant. Thus, the ‘direct track’ is employed only over those fingerprint matches (arrests) for which no detainer was issued, when ICE officials find it in their interest to attempt taking some of the remaining \(H\) types into custody through other means.

The left-over pool of arrested individuals over which the direct track may apply is represented by the distribution in the second table to the right of Figure 2. Similar to the detainer track, only \(H\) types are at play because ICE has no interest over \(L\) types. Although ICE and the county have aligned preferences over the \(Hh\) types, ICE has limited resources and will in general not be undertaking visits to all prisons continuously. We refer to \(v^d\) as the baseline federal enforcement district level probability of an ICE visit to a jail or prison. In other words, \(v^d\) is the district-specific component of the underlying technology through which ICE agents visit local detention facilities searching for unlawfully present immigrants who did not receive a detainer request. Conditional on a visit, the local level will want to collaborate over any \(Hh\) types requested. Thus, unconditionally, \(\Pr(\text{ICE Custody}\mid\text{No Detainer}, Hh) = v^d\). In contrast, the local level may attempt to resist handing over \(H\ell\) arrestees. We will call \(k\) the probability that an \(H\ell\) type is successfully taken into ICE custody conditional on a visit. Notice that \(k\) must depend on a combination of federal and local efforts\(^{31}\). Thus, unconditionally, \(\Pr(\text{ICE Custody}\mid\text{No Detainer}, H\ell) = v^dk\). As such, we observe

\[
\Pr(\text{ICE Custody}\mid\text{No Detainer}) = v^d \frac{(1 - f)\pi^Hh}{1 - (\pi^Hh + \pi^H\ell)f} + v^d k \frac{(1 - f)\pi^H\ell}{1 - (\pi^Hh + \pi^H\ell)f} \equiv P_{C|ND} (11)
\]

\(^{31}\)This allows us to capture in a reduced-form way strategic considerations by ICE agents. For example, they may decide to forgo issuing a detainer request so as not to alert local police agencies of a possible visit.
The detainer and direct tracks are, naturally, not independent. By making the direct track probability \( k \) depend on both federal and local-level immigration enforcement efforts, we allow it to be dependent with the detainer track probabilities \( f \) and \( g \). \( P_{C|ND} \) varies with federal immigration enforcement efforts (through \( v^d, k, \) and \( f \)), with local immigration enforcement efforts (through \( k \)), and with the composition of types in the population of arrestees. As a consequence of this filtering, the resulting pool of individuals in ICE custody from the direct track is represented by the third table to the right of Figure 2. This distribution does not depend on \( v^d \) because the likelihood of a prison visit applies equally for both \( h \) and \( \ell \) types. Once in ICE custody, ICE and the court system determine whether these individuals are deported. Our second and last substantial assumption will be that once under ICE custody, conditional on observables (in particular offense severity) and type \( \{h, \ell\} \), the track through which the arrestee reached ICE custody is irrelevant for the court’s removal decision:

**Assumption 2.** The probability of removal conditional on being under ICE custody does not depend on the track. For \( j \in \{h, \ell\} \),

\[
P(\text{Removal}|\text{ICE Custody, Detainer, } j) = P(\text{Removal}|\text{ICE Custody, No Detainer, } j) \equiv q^j.
\]

We believe assumption 2 is very weak. Once in ICE custody, all individuals are \( H \) types that federal law enforcement is interested in removing. The submission of a detainer could signal a special interest of ICE in the unlawfully present individual. It could also signal, however, the county’s interest in collaborating with the federal level. Thus, conditional on crime severity, the informational content of a detainer issuance is not unambiguous. It is unlikely that courts may want to discriminate between otherwise similar cases of people already in federal custody based only on how they landed into ICE custody. Moreover, recall from section 3 that both detainer and direct tracks exhibit similar patterns of change in the rates at which ICE custodies translate into removals, suggesting similar behavior by the immigration courts. Under this assumption, we can express the probability of a removal conditional on being in ICE custody as

\[
P(\text{Removal}|\text{ICE Custody, No Detainer}) = q^\ell \frac{k \pi^{H\ell}}{k \pi^{H\ell} + \pi^{Hh}} + q^h \frac{\pi^{Hh}}{k \pi^{H\ell} + \pi^{Hh}} \equiv P_{R|C,ND} \quad (12)
\]

The probability in equation (12) is observable as well, and varies with court enforcement -through \((q^\ell, q^h)\)-, with federal enforcement -through \((q^\ell, q^h)\), and \(k\), with local enforcement -through \(k\), and with changes in the distribution of types.

### 4.1.4 Partial Identification from the Direct Track

Our analysis of the immigration enforcement pipeline along the direct track allows us to relate two conditional probabilities \((P_{C|ND}, P_{R|C,ND})\) to five enforcement intensity rates \((v^d, f, k, q^\ell, q^h)\),
and the fraction of $H\ell$ and $Hh$ types in the pool of unlawfully present individuals arrested by local law enforcement. We can re-write these probabilities as:

$$y_1 \equiv P_{C|ND} = v^d \frac{1 - f}{1 - (\pi^{Hh} + \pi^{H\ell}) f} [k\pi^{H\ell} + \pi^{Hh}]$$  \hspace{1cm} (13)

$$y_2 \equiv P_{R|C,ND} P_{C|ND} = v^d \frac{1 - f}{1 - (\pi^{Hh} + \pi^{H\ell}) f} [q^f k\pi^{H\ell} + q^h \pi^{Hh}]$$  \hspace{1cm} (14)

Taking their ratio for observations where the number of removals is not zero, dividing both numerator and denominator by $\pi^{H\ell}$, and using equation (8), we can replace for the preference alignment ratio $\pi^{Hh} / \pi^{H\ell}$, and solve for $k$:

$$k = \frac{(x_2 - x_1) (y_1 q^h - y_2)}{(x_1 - x_2) (y_2 - y_1 q^f)}$$  \hspace{1cm} (15)

Equation (15) shows that $k$ is pinned down by the observables of both detainer and direct tracks, and $(g, q^h, q^f)$. Finally, dividing equation (13) through by equation (5) and replacing for $k$ from equation (15), we eliminate the preference alignment ratio to obtain:

$$v^d \left( \frac{1 - f}{f} \right) = \frac{(1 - x_1)(1 - g)(y_2 - y_1 q^f)}{(x_2 - x_1)g} \left( \frac{q^h}{q^f} \right)$$  \hspace{1cm} (16)

Equation (16) shows that the inverse odds ratio of federal enforcement $f$ is pinned down up to scale by the observables of both detainer and direct tracks, and $(g, q^h, q^f)$. The comparison of rates at which individuals with and without detainers in ICE custody are removed contains the information that allows us to learn about $f$.

We purge selection from equations (10), (15), and (16) by taking ratios of conditional probabilities across steps of the pipeline. This relies on our ability to track the implied changes in the composition of the underlying pool of individuals moving along it within time periods. In an analogy to linear panel settings where taking first differences eliminates fixed effects, here we eliminate the unobserved heterogeneity by taking quotients of steps along the pipeline.

## 5 Identification and Estimation

Our analysis from section 4 shows that the detainer and direct tracks provide us with three relationships (equations (10), (15), (16)) between observable conditional probabilities of transition across stages of the pipeline, $(x_{1ct}, x_{2ct}, x_{3ct}, y_{1ct}, y_{2ct})$, and the six key unobserved immigration enforcement probabilities $(g_{ct}, f_{ct}, k_{ct}, q^f_{ct}, q^h_{ct}, v^d_t)$ for each county-time period $(c, t)$. Crucially, our strategy has allowed us to purge these relationships from the composition of the pool of arrestees $(\pi^{Hh}_{ct}, \pi^{H\ell}_{ct})$ period by period, so even changes over time in what constitutes a high or
low priority individual for the federal or local levels are controlled for. Any endogenous response of the supply of offenses, or of the arresting behavior of law enforcement to immigration enforcement changes, which can directly change the composition of the arrest pool, are similarly controlled for. Thus, our empirical strategy does not assume the exogeneity of criminal or arresting behavior. Cross-county migration of unlawfully present immigrants in response to immigration enforcement pressure in neighboring counties can also impact the arrest pool composition, and thus are controlled for as well. When allowing for unobserved preference misalignment, the structure of the immigration enforcement pipeline and the observed data allow us to control for selection completely non-parametrically, but do not provide enough information to identify each enforcement probability separately. However, notice the triangular structure implied by equations (10), (15), and (16): A given pair \((q^h_{ct}, q^\ell_{ct})\) pins down \(g_{ct}\), and knowledge of \(g_{ct}\) then pins down \(k_{ct}\) and \(v^d_t(1 - f_{ct})/f_{ct}\). Moreover, for any sequence \(\{g_{ct}\}_{t=1}^T\), we recover the time series of preference alignments \(\{\pi^{Hh}_{ct} / \pi^{H\ell}_{ct}\}_{t=1}^T\) using equation (8). We now characterize the identified set for \((q^h_{ct}, q^\ell_{ct})\):

**Proposition 1.** Suppose that \(x_{1ct} > x_{2ct} > x_{3ct} > 0\) and \(y_{1ct} > y_{2ct} > 0\), and define \(\bar{m} \equiv \min\{x_{3ct}/x_{2ct}, y_{2ct}/y_{1ct}\}\), \(\bar{m} \equiv \max\{x_{3ct}/x_{2ct}, y_{2ct}/y_{1ct}\}\), and \(\bar{q} = (x_{1ct}y_{2ct} - x_{3ct}y_{1ct})/y_{1ct}(x_{1ct} - x_{2ct})\). The observed vector of conditional probabilities \(w_{ct} = (x_{1ct}, x_{2ct}, x_{3ct}, y_{1ct}, y_{2ct})\) for a given county-period is consistent with any pair \((q^h_{ct}, q^\ell_{ct}) \in \mathcal{R}(w_{ct})\), where \(\mathcal{R}(w_{ct}) = \mathcal{R}_1 \cup \mathcal{R}_2\), and:

\[
\mathcal{R}_1 = \{(q^h_{ct}, q^\ell_{ct}) : q^h < \bar{m}, \text{ and } q^\ell > \max\{\bar{m}, \bar{q}\}\}
\]

\[
\mathcal{R}_2 = \{(q^h_{ct}, q^\ell_{ct}) : q^h > \bar{m}, \text{ and } q^\ell < \min\{\bar{m}, \bar{q}\}\}.
\]

**Proof.** See Appendix A.

This result follows from jointly imposing all the constraints relating observed moments to unobserved probabilities. This includes the relationships in equations (10), (15), and (16) implied by the immigration enforcement pipeline, together with all probabilities lying inside the unit interval. Each identified set has the same geometric structure, which we illustrate in Figure B.3: two disjoint rectangles, one above and one below the 45-degree line. Its shape illustrates the reason for the lack of non-parametric point identification of the enforcement probabilities based on the immigration pipeline alone: observed conditional probabilities are consistent with a high removal rate for \(\ell\) types and a low removal rate for \(h\) types, or vice versa.

### 5.1 Recovering Enforcement Efforts

We have not yet incorporated into our analysis the relationships across the enforcement probabilities \((g_{ct}, f_{ct}, k_{ct}, v^d_t, q^\ell_{ct}, q^h_{ct})\) that are also implied by the immigration enforcement process, and
driven by the unobserved enforcement effort choices of the local and federal levels. First, the sources of covariation between probabilities: across the detainer and direct tracks, i) $g_{ct}$ should covary with $k_{ct}$ through the immigration enforcement effort of the local level; ii) $f_{ct}$ should covary with $k_{ct}$ through the immigration enforcement effort of the federal level; iii) $q^\ell_{ct}$ and $q^h_{ct}$ should covary with $f_{ct}$ through the immigration enforcement effort of the federal level. Second, the following exclusion restrictions: i) $g_{ct}$ should not vary with federal enforcement efforts; ii) $f_{ct}$ should not vary with local enforcement efforts; iii) $v^d_t$ should not vary across counties within a federal enforcement district; iv) $q^\ell_{ct}$ and $q^h_{ct}$ should not vary with local enforcement efforts.

We exploit the information from these additional implications of the deportation process through parametric restrictions. We denote the local level enforcement effort by $\epsilon_{ct}$, and the federal level enforcement effort by $\xi_{ct}$. For computational convenience, we model the enforcement probabilities as logistic functions of observable county characteristics $x_c$, and the corresponding enforcement efforts. We can directly work with the log odds forms:

\[
\log \left( \frac{f_{ct}}{1-f_{ct}} \right) \equiv \tilde{f}_{ct} = x'_c \beta^f + \xi_{ct} \tag{17}
\]

\[
\log \left( \frac{g_{ct}}{1-g_{ct}} \right) \equiv \tilde{g}_{ct} = x'_c \beta^g + \epsilon_{ct} \tag{18}
\]

\[
\log \left( \frac{k_{ct}}{1-k_{ct}} \right) \equiv \tilde{k}_{ct} = x'_c \beta^k + \kappa_\epsilon \epsilon_{ct} + \kappa_\xi \xi_{ct} + \eta_{ct} \tag{19}
\]

\[
\log \left( \frac{q^\ell_{ct}}{1-q^\ell_{ct}} \right) \equiv \tilde{q}^\ell_{ct} = x'_c \beta^{q\ell} + \gamma^\ell \xi_{ct} + \zeta^\ell_{ct}, \quad \tau \in \{\ell, h\} \tag{20}
\]

where $\beta \equiv (\beta^f, \beta^g, \beta^k, \beta^{q\ell}, \beta^{qh})$, the $(\beta, \kappa_\epsilon, \kappa_\xi, \gamma^h, \gamma^f)$ are regression coefficients, and $(\eta_{ct}, \zeta_{ct})$ are errors. The $\zeta_{ct}$ capture the enforcement efforts of immigration courts unrelated to ICE efforts. Recall from equation (16) that we do not directly have an expression for $f_{ct}$, but rather for $\overline{f}_{ct} \equiv v^d_t (1 - f_{ct}) / f_{ct}$. Re-writing equation (17) in terms of $\overline{f}_{ct}$,

\[
\log (\overline{f}_{ct}) \equiv \overline{\tilde{f}}_{ct} = \log (v^d_t) - x'_c \beta^f - \xi_{ct} \tag{21}
\]

so district fixed effects in equation (21) recover the district-level ‘prison visit’ probabilities.

Suppose we knew $(q^\ell_{ct}, q^h_{ct})$ for all $(c,t)$, which we collect in the vectors $(q^\ell, q^h)$. Then we could directly compute $g_{ct}$, $\overline{f}_{ct}$, and $k_{ct}$ for each $(c,t)$, allowing us to estimate the regressions in equations (18) and (21). From these we could then recover the $\epsilon_{ct}$ and $\xi_{ct}$ as residuals:

\[
\hat{\epsilon}_{ct} = \delta^d_{t,0ls} - x'_c \beta^f_{0ls} - \overline{\tilde{f}}_{ct}, \quad \hat{\xi}_{ct} = \tilde{g}_{ct} - x'_c \beta^g_{0ls}
\]

\[32\]The logistic choice allows us to recover the relevant coefficients as closed forms from the corresponding log odds linear regressions, but any choice of functional form for the enforcement probabilities would suffice.
where $\delta_{t, \text{ols}}$ are federal district by period fixed effects. A plot of the $\epsilon_{ct}$ on the $\xi_{ct}$ over time for a given county would then reveal the shape of the county’s best response. The vectors of immigration enforcement efforts $\hat{\xi}(q^f, q^h; W, X)$ and $\hat{\epsilon}(q^f, q^h; W, X)$ are thus closed-form functions of $(q^f_{ct}, q^h_{ct})$, $W = (w_1, \ldots, w_n)$ where $w_c = (w'_{ct}, \ldots, w'_{ct})'$, and $X = (x'_1, \ldots, x'_n)'$. Using these enforcement efforts as regressors, we could then estimate regressions (19)-(20). The minimized sums of squared residuals of these regressions are thus closed-form functions of $(q^f_{ct}, q^h_{ct})$, $W$, and $X$ exclusively:

$$S^k(q^f, q^h; W, X) = \sum_{c} \sum_{t} (\hat{\kappa}_{ct} - x'_c \beta_{ols}^k - \kappa_{e, \text{ols}} \hat{\epsilon}_{ct} - \kappa_{\xi, \text{ols}} \hat{\xi}_{ct})^2$$

$$S^f(q^f, q^h; W, X) = \sum_{c} \sum_{t} (\hat{\alpha}_{ct} - x'_c \beta_{ols}^f - \gamma_{\text{ols}} \hat{\epsilon}_{ct})^2$$

$$S^h(q^f, q^h; W, X) = \sum_{c} \sum_{t} (\hat{\sigma}_{ct} - x'_c \beta_{ols}^h - \gamma_{\text{ols}} \hat{\xi}_{ct})^2$$

We can define $S = S^k + S^f + S^h$, and proceed to choose the vectors $(q^f, q^h)$ to maximize the fit of equations (19)-(20) over the identified sets $\mathcal{R}(w_{ct})$ for each observation:

$$\min_{(q^f, q^h) \in \times_{ct} \mathcal{R}(w_{ct})} S(q^f, q^h; W, X) \tag{22}$$

This is a high-dimensional search. However, our objective function is in closed form, and easily evaluated at any given $(q^f, q^h)$. It is also strictly convex and thus has a unique minimum. Moreover, the search over each element of the vectors $(q^f, q^h)$ is highly constrained by its corresponding identified set $\mathcal{R}(w_{ct})$. Our ability to go from the partial identification result in Proposition 1 to the point identification result from the solution to equation (22) relies on two features of equations (17)-(20): i) the exclusion restrictions provided by the immigration enforcement pipeline allowing us to recover the unobserved enforcement efforts of the local and federal levels at a given pair $(q^f, q^h)$; ii) the assumption that the coefficients $\beta$ on the county characteristics in these equations (which capture the heterogeneity along observables in the response of the enforcement probabilities to the local and federal efforts) are homogeneous across counties. The constancy of these coefficients across counties implies that at a given $(q^f_{ct}, q^h_{ct})$ for all county-periods except for $(c, t)$, the implied value of $\beta$, common across all observations, pins down what the best pair $(q^f_{ct}, q^h_{ct}) \in \mathcal{R}(w_{ct})$ must be for solving equation (22).

We implement this procedure separately for minor and serious offenses, recovering federal and local enforcement efforts over both: $(\xi^m, \xi^s)$ and $(\epsilon^m, \epsilon^s)$.\footnote{We use a particle swarm optimizer to minimize equation (22), which is ideal for optimizing a high-dimensional function inside a bounded support.} We then recover the implied immigration enforcement probabilities for minor and serious offense cases $\{g, f, k, q^f, q^h, v^d\}_m$, $\{g, f, k, q^f, q^h, v^d\}_s$, and the corresponding strengths of covariation between these probabilities

\item We use a particle swarm optimizer to minimize equation (22), which is ideal for optimizing a high-dimensional function inside a bounded support.
Finally, we recover the coefficients \((\beta_m, \beta_s)\) capturing the patterns of heterogeneity in the effects of local and federal enforcement efforts across observable characteristics, on the immigration enforcement probabilities.

The identification of the regression coefficients and the distributions of local and federal enforcement efforts from equations (17)-(20) follows from comparing the implied rates of movement along steps of the pipeline of counties with similar characteristics. When, for example, two similar counties face different implied values for \(f_{ct}\), we can attribute it to differences in federal efforts, \(\xi_{ct}\), because these relationships have already controlled for selection as they do not depend on \((\pi^H, \pi^{Hh})\).

6 Estimation Results

Our empirical strategy allows us to recover the local immigration enforcement response to changes in federal immigration enforcement efforts. We do so exploiting the variation in rates at which arrested unlawfully present individuals move along the deportation process, allowing us to control for selection. This strategy, however, is demanding on the data. As Proposition 1 indicates, we can only purge selection from periods in which we observe strictly positive counts of immigration enforcement activity at all stages of the immigration enforcement pipeline. This, naturally, limits the external validity of our findings. The sample for which periods with positive counts of detainers, ICE custodies with and without detainers, and removals with and without detainers are all positive, is composed of counties with relatively large populations, and relatively large populations of unlawfully present immigrants.

In panel B of Table B.2 we report summary statistics for the resulting sample of counties with observed data satisfying the conditions required for identification. Our estimation sample is composed of counties with somewhat larger populations than the average county, and 30 percent larger undocumented population than the average county (2.2 compared to 1.7 percent undocumented share). It is also slightly more educated, but not much more Democratic than the average county (43 compared to 41 percent Democratic share). However, the average county in our sample is considerably less rural than average, and has a significantly larger services sector. The results below are not representative of the smaller, more rural communities in the US. Figure B.4 similarly presents a county-level map of the US, where we highlight the counties included in this sample. Despite the limitations just highlighted, the map reveals a wide regional coverage. As expected, Texas, Florida, the Southwestern US and the Northeast are heavily represented in our estimation sample. In Appendix Table B.4 we also report summary statistics for the data moments \(\mathbf{w}_{ct}\) in our estimation sample. On average, enforcement outcomes are lower in the post-guidelines period at every stage along the immigration enforcement pipeline, except for minor offenses in the direct track. Perhaps surprisingly, these average falls are larger
for serious offenses. Along the detainer track, for example, the probability of a removal at the mean fell from 8.3 to 5.1 percent; it fell even more along the direct track, from 33 to 19 percent. Our empirical strategy allows us to decompose the sources of variation driving these changes.

### 6.1 Enforcement Probabilities and Best Responses

In panel A of Table 2 we present average estimates of the immigration enforcement rates by type of offense and period. Panel B reports the estimated coefficients from equations (19) and (20) capturing the covariation between local and federal enforcement along the detainer and direct tracks, and between federal efforts and immigration court outcomes.\(^{34}\) Average detainer issuance rates \(f\) fell 3 percentage points for minor offenses after the guidelines were issued, and increased 9 percentage points for serious offenses. These changes are in line with the purported objective of ICE’s change in guidelines, but for minor offenses are smaller than the guidelines themselves suggested. Especially for serious offenses, we find a large change in the average

---

\(^{34}\)In Tables Table B.5 and Table B.6 we report the corresponding estimates of the \(\beta\) coefficients on our vector of covariates in equations (17)-(20). Our inference for the coefficients in these equations accounts for the presence of \(\epsilon\) and \(\xi\) as generated regressors. We present the derivation of these analytic standard errors in Appendix A.2.
Table 3: Local Best Responses: Pooled vs. Fixed Effects. The table presents regression results for the local immigration enforcement effort of the county \( \epsilon \) on the federal immigration enforcement effort of ICE \( \xi \). Odd columns present pooled estimates across all counties, while even columns present county fixed-effects estimates. The first two columns present results for minor offenses, while the last two columns present results for serious offenses. Standard errors for these coefficients are reported in parentheses.

rate of compliance with detainers, \( g \), which fall by 11 percentage points. On the other hand, we estimate falls in average preference alignment \( \pi^{Hh}/\pi^{H\ell} \) for both levels of offenses, with an especially large fall for serious offenses. This suggests that while the fall in immigration enforcement outcomes related to minor offenses following the change in guidelines was mostly driven by the relaxation of federal efforts, the fall in immigration enforcement outcomes related to serious offenses was driven by an offsetting response of the local level to increased federal efforts over these types of cases, and a concomitant increase in conflict between levels.

It is likely that a major force driving the fall in alignment over serious offenses was a change in ICE’s removal priorities related to offense severity. If an individual who previously was not of interest to ICE, and thus, about whom there was little disagreement between the federal and local levels, becomes of interest to ICE, this creates a divergence in the preferences of both levels over the case. The table also suggests that the federal level increased enforcement over serious offenses along both detainer and direct tracks (average \( k \) increased by 6 percentage points). This is consistent with the decreased collaboration of the local level, because avoiding the use of detainers through the direct track partially allowed ICE to undermine local level resistance.

Turning our attention to Panel B, we find that federal efforts lead to a positive covariation between \( f \) and \( k \), while local efforts lead to a negative covariation between \( g \) and \( k \). The table also suggests that immigration court preferences did not change with the introduction of the federal guidelines. These are more aligned with county level than with federal level preferences: at the mean, \( q^{h} > q^{\ell} \). On the other hand, we find that \( \xi \) leads to a negative covariation between \( f \) and \( q^{h} \), and to a positive covariation between \( f \) and \( q^{\ell} \). In periods of strong federal enforcement, the courts do move in the direction of making more likely the removal of individuals that the local level would rather not deport.

We find strong evidence of strategic substitutabilities in the response of the local level to increased federal enforcement. Because our approach allows us to recover \( \xi \) and \( \epsilon \) at different points in time for each county, and because the structure of the pipeline makes the county’s col-
Figure 3: Scatterplot of Local Efforts on Federal Efforts. Panel (a) shows the scatterplot corresponding to column (1) in Table 3, plotting $\epsilon$ on $\xi$ for arrestees charged with minor (levels 2 and 3) offenses. Panel (b) shows the scatterplot corresponding to column (3) in Table 3, plotting $\epsilon$ on $\xi$ for arrestees charged with serious (level 1) offenses. Points in blue represent counties above median Democratic vote share, and points in red represent counties below median Democratic vote share. The curves are non-parametric best-fit regression lines for each group of counties.

Laboration decision happen after ICE has made a detainer decision, we can directly reconstruct movements along the ‘best response’ curve of the county. In Table 3 we present our main estimates of the average slope of this best response across counties, from models where we regress $\epsilon$ on $\xi$. We report separately the responses over each type of offense, finding substitutabilities in both cases, but larger responses for minor offenses. Even columns in the table report county fixed effects models, that effectively compute the slope for each county and average over those slopes. For minor offenses, we find that a one standard deviation higher federal enforcement leads to 1.3 standard deviations less local enforcement. For serious offenses, we find a similarly negative local level response of 0.6 standard deviations. The local level response in most counties partially undoes the federal effort. Both coefficients are precisely estimated.

We argued above that our empirical strategy allows us to distinguish selection from enforcement. In the odd columns of the table we report the results of running a pooled regression of $\epsilon$ on $\xi$, allowing us to indirectly assess the validity of our claim: in the pooled model, county-level fixed effects are in the error term. For both levels of offenses, the magnitudes of the pooled and fixed effects coefficients are very close to each other, showing that $\xi$ is effectively uncorrelated with fixed county-level unobservables. The results from Table 3 motivate us to present in Figure 3 the scatterplots corresponding to the pooled regressions, where we distinguish between counties above (blue) and below (red) median Democratic vote share.

6.2 Heterogeneity in the Local Enforcement Response

Counties with different preferences should be expected to respond differently to federal enforcement. How much heterogeneity is there in the nature of the local-level enforcement response? Figure 4 plots the county-level distribution of slopes, which we recover directly from linearly fitting $\epsilon$ to $\xi$ county by county. For both minor and serious offenses cases, around 80 percent of
Figure 4: Distribution of Best Response Slopes Across Counties. The figures show the distribution of county slopes for a regression of $\epsilon$ on $\xi$. Panel (a) is for cases of arrestees charged with minor (levels 2 and 3) offenses. Panel (b) is for cases of arrestees charged with serious (level 1) offenses.

counties exhibit negative slopes, indicating strategic substitutability. The remainder 20 percent of counties show positive slopes, indicating strategic complementarity.

To investigate the main drivers of the heterogeneity in the shape of these best responses, in Table 4 we present results of cross-sectional regressions for the slopes of each county’s best response on a battery of county characteristics related to local preferences over immigration policy. In columns 1 and 4 we include only a constant and the Democratic vote share (−50 percent). The constant captures the average best response slope for a perfectly competitive county. More Democratic counties exhibit significantly more negative best responses for serious offenses. In columns 2 and 5 we then add the Hispanic share of the population. Perhaps surprisingly, conditional on Democratic support, counties with larger Hispanic populations have less negative slopes for minor offenses. Lastly, in columns 3 and 6 we include the undocumented share (which is highly correlated with the Hispanic share), log population, the share with a bachelor’s degree, a rural county dummy, the share of employment in the services sector, log distance to ICE and a dummy for the existence of a 287(g) cooperation agreement with the federal government. The inclusion of these controls makes the coefficient on the Democratic share negative for both kinds of offenses, making it clear that aggregate partisan preferences are the main driver of the local-level response. In counties with larger undocumented populations, in contrast, the best response for serious offenses is less negatively sloped.\textsuperscript{35} These findings highlight the importance of the local response to federal enforcement efforts, and rationalize why immigration enforcement outcomes under Secure Communities varied widely across space.

\textsuperscript{35}In principle an important covariate capturing political economy considerations is whether the county elects or appoints its sheriff. Among our sample of counties, however, 98 percent of them elect their sheriff so we omit this variable from our set of covariates.

Table 4: Heterogeneity in Local Best Responses. The table shows regression coefficients for the slopes of the best response of $\epsilon$ to $\xi$, separately for minor and serious offenses. The dependent variable in all specifications is the slope of a regression of $\epsilon$ on $\xi$ and a constant for each county. Each observation corresponds to a county. Regressions are weighted by the number of time periods used to estimate each slope. The explanatory variables include a constant and several county characteristics. Log Population is taken from the 2010 Census. Undocumented share is an estimate of the number of unlawfully present individuals in 2010. Democratic party share is an average of the 2008 and 2012 Democratic Presidential vote shares minus 50 percent, taken from David Leip’s Electoral Atlas. Bachelor degree share is measured as the fraction of the adult population with at least a bachelor’s degree. Hispanic share is measured as the fraction of the population who is Hispanic. Services share is measured as the fraction of the employed population working in the services sector. Bachelor degree share, Hispanic share, and Services share are taken from the 2006-2010 waves of the American Communities Survey. Rural is a dummy variable indicating whether the county is considered non-metropolitan according to the National Center for Health Statistics at the Center for Disease Control. Distance to ICE office is measured as the log of the number of miles between the county centroid and the county centroid of the corresponding ICE district office seat, and computed directly by us. 287(g) Program is a dummy variable indicating whether the county or any city in the county was ever part of the 287(g) program, taken from Steil and Vasi (2014).

6.3 Patterns of Unobserved Heterogeneity

Now we discuss our findings related to the patterns of unobserved heterogeneity in immigration enforcement. Our measure of preference alignment, $\pi_{Hh}/\pi_{Hl}$, is strongly positively correlated with federal immigration enforcement efforts $\xi$. We illustrate this in Figure 5 where we plot the unconditional scatterplots between both variables. Panel (a) presents the scatterplot for minor offenses, and panel (b) for serious offenses. We confirm the robustness of this correlation in the first three columns of Table 5. There we report panel regressions of federal efforts on preference alignment. The first column reports the unconditional relationship. In the second column we
Figure 5: The Nature of Selection: Preference Alignment and Federal Immigration Enforcement Efforts. The figure shows the relationship between log preference alignment and federal immigration enforcement efforts, pooled across county-time periods. Panel (a) is for arrestees charged with minor (levels 2 and 3) offenses, and corresponds to the results reported in column (1) of panel A in Table 5. Panel (b) is for arrestees charged with serious (level 1) offenses, and corresponds to the results reported in column (1) of panel B in Table 5.

The coefficient is 0.85 (s.e. = 0.01), for both minor and serious offenses. This is a key result of our analysis. ICE is extremely good at targeting its enforcement efforts towards places where those efforts will be highly effective (where the composition of the arrest pool is such that ICE can expect a high degree of local-level cooperation). This is perhaps not as surprising considering the informational advantage that ICE acquired under Secure Communities and its access to massive law enforcement databases. At the same time, the strong willingness of the federal level to direct efforts toward places where it expects collaboration also indicates that the local level is a key gatekeeper for immigration enforcement.

In columns 4-9 of Table 5 we complement these results showing that the negative unconditional correlation between local efforts $\epsilon$ and preference alignment $\pi_{Hh}/\pi_{H\ell}$ is completely driven by federal immigration efforts $\xi$. Column 4 reports the unconditional regression coefficient, which is negative and statistically significant. This is also the case after introducing county fixed effects in columns 5-6. In columns 7-9, controlling for federal efforts $\xi$, the negative relationship between local efforts and preference alignment vanishes. We interpret this exercise as an additional specification test of our model. It reassures us that the best responses we recovered can be interpreted causally, and that our model of the immigration enforcement pipeline is a good approximation to the actual operation of the process.

We conclude this section examining whether our measure of preference alignment between the federal and local levels, $\pi_{Hh}/\pi_{H\ell}$, is correlated with other observables. This allows us to establish how characteristics of the arrestee pool shape the conflict over immigration policy. In Table 6 we estimate county fixed-effects regressions of log($\pi_{Hh}/\pi_{H\ell}$) for minor and serious offenses cases on interactions between a post-guidelines dummy and the Democratic vote share.

---

36In column three we find no difference in this relationship before and after the change in ICE guidelines.

Table 5: Correlation between preference alignment and immigration efforts. The table shows regression coefficients for panel regressions of federal and local immigration enforcement efforts on the log of preference alignment $\pi_{Hh}/\pi_{H\ell}$. Panel A reports results for cases involving minor offenses, while panel B reports results involving serious offenses. In columns 1-3 the dependent variable is the federal effort $\xi$. In columns 4-9 the dependent variable is the local effort $\epsilon$. Columns 2, 3, 5-9 include county-level fixed effects. Columns 3, 6, and 9 additionally include an interaction term between preference alignment and a dummy for the period following the federal guidelines change. Columns 7-9 additionally include federal immigration efforts $\xi$ as a regressor. The reported standard errors are robust to arbitrary heteroskedasticity.

the Hispanic population share, and the share with a bachelors degree. We then additionally include measures of three salient observed characteristics of the pool of unlawfully present arrestees which vary at the county-semester level: the fraction of detainers issued against Mexican and Central American nationals, and the fraction issued against young (less than 30 years old) unlawfully present immigrants. During our period of study, Mexican and Central American nationals constitute the bulk of unlawfully present immigrants, with the fraction of Central Americans growing over time.\(^{37}\) Around 65 and 18 percent of all detainers in our sample period were issued against Mexicans and Central Americans. Similarly, young individuals constitute around 40 percent of all detainers in our sample.\(^{38}\)

Columns 1 and 4 of Table 6 show that in the post-guidelines period, the Democratic share predicts increased preference misalignment over immigration enforcement. In contrast, condi-

\(^{37}\)Central American nationals include individuals from any of the following countries: Belize, El Salvador, Guatemala, Honduras, Nicaragua, and Panama.

\(^{38}\)Our detainer data also reports the sex of the unlawfully present arrestee. Because more than 95 percent of them are males on average, we do not include this covariate in the analysis.
### Table 6: Preference alignment and observable characteristics.

The table reports coefficients for county fixed effects models. The dependent variable is log of preference alignment $\pi_{Hh}/\pi_{Hl}$, for minor offenses cases (columns 1-3), and serious offenses cases (columns 4-6). Each observation corresponds to a county-semester. Explanatory variables include: county and semester fixed effects, county characteristics interacted with the policy change and time varying county-specific covariates. Democratic share is an average of the 2008 and 2012 Democratic Presidential vote shares minus 50 percent. Bachelor share is measured as the fraction of the adult population with a bachelor’s degree or more. Bachelor and Hispanic share are taken from the 2006-2010 waves of the American Communities Survey. Guidelines is a dummy variable indicating the semesters after the guidelines change. Mexican and Central American shares are the fractions of detainers issued against immigrants of those nationalities in the county-semester. Young share is the fraction of detainers issued against immigrants less than 30 years old. All categories of offenses (no criminal conviction, drug possession, traffic violations, immigration violations for minor and assaults, drug trafficking, burglary and smuggling aliens for serious) are shares of detainers issued against unlawfully present immigrants in the county-semester. The omitted categories include all other offenses minor or serious offenses. Standard errors are robust to arbitrary heteroskedasticity.

</table>

The dependent variable is the log of preference alignment $\pi_{Hh}/\pi_{Hl}$, for minor offenses cases (columns 1-3), and serious offenses cases (columns 4-6). Each observation corresponds to a county-semester. Explanatory variables include: county and semester fixed effects, county characteristics interacted with the policy change and time varying county-specific covariates. Democratic share is an average of the 2008 and 2012 Democratic Presidential vote shares minus 50 percent. Bachelor share is measured as the fraction of the adult population with a bachelor’s degree or more. Bachelor and Hispanic share are taken from the 2006-2010 waves of the American Communities Survey. Guidelines is a dummy variable indicating the semesters after the guidelines change. Mexican and Central American shares are the fractions of detainers issued against immigrants of those nationalities in the county-semester. Young share is the fraction of detainers issued against immigrants less than 30 years old. All categories of offenses (no criminal conviction, drug possession, traffic violations, immigration violations for minor and assaults, drug trafficking, burglary and smuggling aliens for serious) are shares of detainers issued against unlawfully present immigrants in the county-semester. The omitted categories include all other offenses minor or serious offenses. Standard errors are robust to arbitrary heteroskedasticity.
tional on the Democratic vote share, the Hispanic share is a positive predictor of increased preference alignment in this period. Columns 2 and 5 then show that higher shares of Mexicans, Central Americans, and young individuals, predict falls in preference alignment, and thus, more conflict over immigration enforcement. These averages, however, mask considerable heterogeneity: among the most Democratic counties, a large share of Mexicans in the pool increases alignment for minor offenses. In contrast, in the most Democratic counties large shares of Central American arrestees sharply decrease preference alignment. These patterns could arise if, for example, while the federal level is relatively indifferent between otherwise similar Mexicans and Central Americans, more Democratic counties are less willing to remove Mexicans, and, at the same time, do not favor the rising presence of Central American immigrants.

6.4 Counterfactual Exercise: No Change in the ICE Guidelines

We now assess the effects of the 2011 change in ICE enforcement priorities under a counterfactual exercise exploring how the outcomes of immigration enforcement under Secure Communities would have evolved in the absence of a change in guidelines. Within our framework, the policy change manifests itself in two ways: first, changes in preferences over the pool of arrestees (in particular over our measure of preference alignment) reflect changes in ICE removal priorities. Second, the federal enforcement efforts, may have changed in response to the shock to the policy environment. This is, the underlying relationship between preference alignment $\pi_{Hh}/\pi_{Hf}$ and federal efforts $\xi$ may have changed in the post-guidelines period.

Thus, we take the recovered relationship between $\xi$ and $\pi_{Hh}/\pi_{Hf}$ across counties in the pre-guidelines period (by regressing $\xi$ on $\pi_{Hh}/\pi_{Hf}$), and use it to predict the federal enforcement efforts $\hat{\xi}$ in the post-guidelines period that would have occurred under the actual $\pi_{Hh}/\pi_{Hf}$’s, were the pre-guidelines regime still to hold. In this way we hold selection constant. With these counterfactual federal efforts for the post-guidelines period we then use the best responses for each county to predict the counterfactual local enforcement efforts $\hat{\epsilon}$ that would have been observed in response to these federal efforts.\(^{39}\) Armed with these $\hat{\epsilon}$’s and $\hat{\xi}$’s, and using our parameter estimates, we recover the implied counterfactual enforcement probabilities $\{\hat{f}, \hat{g}, \hat{k}, \hat{q}^h, \hat{q}^f\}$. Finally, combining the recovered preference alignments with these counterfactual enforcement probabilities, we recover the counterfactual immigration enforcement outcomes $\mathbb{P}(\text{ICE Custody}|\text{Detainer})$, $\mathbb{P}(\text{Removal}|\text{ICE Custody, Detainer})$, and $\mathbb{P}(\text{Removal}|\text{ICE Custody, No Detainer})$ using equations (3), (4), and (12).\(^{40}\)

In Figure 6 we present the results of this counterfactual exercise. Each subfigure plots the

\(^{39}\)Notice that while the first step where we obtain counterfactual $\hat{\xi}$’s based on $\pi_{Hh}/\pi_{Hf}$ is purely predictive, the second step that recovers counterfactual $\hat{\epsilon}$’s based on $\hat{\xi}$’s is causal.

\(^{40}\)We cannot recover the baseline rates $\mathbb{P}(\text{Detainer}|\text{Arrest})$ or $\mathbb{P}(\text{ICE Custody}|\text{No Detainer})$ from equations (2) and (11) of each track because we only observe $\pi_{Hh}/\pi_{Hf}$ but not $\pi_{Hh}$ and $\pi_{Hf}$ separately.
Figure 6: Counterfactual Evolution of Immigration Enforcement Outcomes in the Absence of Guideline Changes.

The figure plots the evolution over time of the distribution of immigration enforcement outcomes across counties. The distributions of outcomes predicted by the model are depicted in shades of blue. The distributions of counterfactual outcomes in the absence of guideline changes are depicted in shades of red. The lightest shade regions represent the 10th to 26th and 74th to 90th quantiles. The intermediate shade regions represent the 26th to 42nd and 58th to 74th quantiles. The darkest shade region represents the 42nd to 58th quantiles. The top three panels depict the distributions for minor offenses cases. The bottom three panels depict the distributions for serious offenses cases.
The time evolution of the cross-county distribution of an immigration enforcement outcome along the pipeline. The top panel presents plots for minor offenses cases, while the bottom panel presents plots for serious offenses cases. Panel a illustrates a 5 percentage points across-the-board downward shift of the distribution of $P(\text{ICE Custody}|\text{Detainer})$. In the absence of the guidelines, federal efforts $\xi_{\text{minor}}$ are predicted to be higher for most counties (see Figure B.5). Strategic substitutability in the local best response of most counties implies reduced collaboration towards minor offenses cases, resulting in lower numbers of $\ell$-type arrestees being passed down into ICE custody after a detainer issuance ($g$, on average, would have fallen considerably).

The direct consequence of lower local collaboration with ICE can be gauged in panel b. The distribution of $P(\text{Removal}|\text{ICE Custody, Detainer})$ shifts upwards by around 2 percentage points. This increase in the overall probabilities of removal at the ICE custody stage following a detainer issuance results from a selection effect that interacts with court-level preferences: the weakening of local efforts means that the pool of arrestees that moves onto ICE custody becomes selected towards more $h$ types relative to $\ell$ types. Because on average $q^h > q^\ell$ (see Table 2), the pool of unlawfully present immigrants facing the removal stage is composed of people more likely be removed, making the conditional removal rate go up.\footnote{Of course, this exercise supposes court-level preferences remain unchanged under no change in guidelines.}

In contrast, the opposite pattern takes places along the direct track. Panel c illustrates that the distribution of $P(\text{Removal}|\text{ICE Custody, No Detainer})$ shifts down by 4 percentage points. This happens because along the direct track, higher federal efforts, $\xi_{\text{minor}}$, and lower local efforts, $\epsilon_{\text{minor}}$, both increase $k$ (see Table 2), generating a selection effect over the pool of individuals in ICE custody without a detainer shifting its composition towards relatively more $\ell$-types. Because $q^h > q^\ell$, this pool is less removable from the point of view of the courts.

Under our counterfactual, outcomes for serious offenses cases behave differently. Panel d of Figure 6 shows that the counterfactual distribution of $P(\text{ICE Custody}|\text{Detainer})$, exhibits something close to a mean-preserving spread, of around a fifth of a standard deviation of the predicted distribution. The increased variance under the counterfactual results from mean reversion of our counterfactual federal enforcement efforts: as panel b in Figure B.5 illustrates, county-periods with low predicted federal enforcement have higher than average counterfactual federal enforcement, and vice-versa. As a result, the local enforcement response is heterogeneous across counties: county-periods with relatively low predicted federal enforcement see their counterfactual local enforcement fall, while county-periods with relatively high predicted federal enforcement see their counterfactual local enforcement increase. On aggregate, these effects do not shift the counterfactual distribution of $P(\text{ICE Custody}|\text{Detainer})$, but they do increase its variance. The magnitude of this spread, however, is not as large because, as we reported in Table 3, the average best response slope for serious offenses cases is considerably smaller than for minor offenses cases, leading to a more nuanced response from the local level.
In panel e we then observe an upward shift of around 4 percentage points in the counterfactual distribution of \( P(\text{Removal} | \text{ICE Custody, Detainer}) \) along the detainer track. This aggregate shift results from how removal rates respond to changes in federal enforcement efforts, and not from a systematic selection effect as was the case for minor offenses cases. In particular, from Table 2, notice that for serious offenses, \( q^\ell \) is an increasing function, whereas \( q^h \) is a decreasing function of \( \xi^{\text{serious}} \). Thus, for counties that would have experienced increased federal efforts, on average the resulting increase in \( \ell \)-type removals more than offsets the decrease in \( h \)-type removals. Analogously, for counties that would have experienced decreased federal efforts, on average the resulting increase in \( h \)-type removals more than offsets the decrease in \( \ell \)-type removals. The absence of guidelines would have magnified the local-federal conflict over immigration enforcement in the following sense: places where the local level reacts by weakening enforcement end up seeing the removal of relatively more \( \ell \) types, precisely the types of unlawfully present immigrants that the county would prefer not to be removed.

Finally looking at panel f, we observe a small downward shift of the counterfactual distribution of \( P(\text{Removal} | \text{ICE Custody, No Detainer}) \) along the direct track, particularly in the last semesters under consideration. Besides \( q^\ell \) and \( q^h \), \( k \) also changes with both federal and local efforts. For serious offenses cases, the strategic substitutability response of most counties reinforces the effect that federal efforts have on the rate at which arrested individuals move onto ICE custody (we estimate \( k \) to be increasing in \( \xi \) and decreasing in \( \epsilon \)). As a result, in counties where \( q^\ell \) falls in response to weakened federal enforcement, \( k \) also falls leading to relatively less \( \ell \) types removed, and on aggregate a lower removal rate. This exercise illustrates that even holding the distribution of the underlying pool of arrestees constant, the screening forces induced by the immigration enforcement pipeline interact with preferences at the court stage in such way that had the guidelines not changed in 2011, the patterns of immigration enforcement outcomes resulting from the equilibrium responses of the local level would have antagonized the average large and urban county even more than we observed.

We can use our counterfactual exercise to compute for each county-time period following the change in guidelines, the counterfactual percent difference in number of deportations relative to the baseline prediction. As we show in Appendix A.3, this quantity is identified. This exercise holds constant the composition of the pool of arrested unlawfully present immigrants. Thus, it is informative about the impact of the change in federal guidelines that can be attributed to the endogenous response of the local level and the subsequent screening effects taking place down the pipeline. Figure B.6 plots the resulting distributions of percent differences for minor and serious offenses cases, across all county-time periods after 2011-II. Recall that the change in guidelines purported to relax enforcement towards minor offenses cases, and redirect it towards serious offenses cases. In the absence of such a policy change, but holding fixed any effects the policy may have had over the composition of the arrest pool, counties on average would
Figure 7: Evolution of Local immigration enforcement efforts and the California Trust Act. The figure plots the evolution over time of the median of the estimated local immigration enforcement efforts $\epsilon$ across counties. The red line depicts the median for California counties. The blue line depicts the median for all other US counties. The vertical black line represents the semester of implementation of the Trust Act. Panel a reports the medians for minor offenses cases. Panel b reports the medians for serious offenses cases. The number of California counties is 30 for minor offenses and 24 for serious offenses. The number of non-California counties is 447 for minor offenses and 199 for serious offenses.

have experienced 8.6 and 41 percent more removals for minor and serious offenses cases. Across county-semesters, more than 60 percent would have experienced strictly more removals in the absence of the federal guideline change. A quarter of county-semesters would have observed removals to be more than 50 percent higher. Thus, in the absence of a change in preferences over removal priorities, the countervailing response of the local level would not have been enough to reduce removals if the federal level had kept the direction of its enforcement efforts unchanged.

6.5 Model Validation: The California Trust Act

We conclude with a validation exercise for our model, based on California’s Trust Act. This law passed in 2013 and came into effect on January 2014. It imposed stringent limits on local-level collaboration with detainer requests from ICE. Under the Trust Act, local police are only allowed to honor detainers falling into a specific list of relatively serious offenses. Our model does not account for the passage of the Trust Act, giving us an opportunity to assess whether our estimates of local immigration enforcement efforts do capture the patterns we expected to have taken place under this law. Figure 7 presents the evolution over time of the median of our estimated local immigration enforcement efforts $\epsilon$, distinguishing between California counties (in red) and all other counties (in blue) in our sample. The vertical line indicates the activation of the Trust Act. As expected, local efforts over minor offenses cases fall sharply for California counties at the time of the policy change, which we illustrate in panel a. The

\footnote{For a detailed description of the Trust Act and the list of offenses for which the county officials are allowed to cooperate with ICE, see \textit{California (2014)}.}
Trust Act allowed local law enforcement to collaborate with ICE for the most serious offenses cases, however. Consistent with our expectations, panel b shows that for serious offenses cases, California counties experienced a decline in local effort not dissimilar to what happened in the rest of the US. We see these results as validating the ability of our model to capture accurately the patterns of immigration enforcement under Secure Communities.

7 Concluding Remarks

We study immigration enforcement under the Secure Communities program, as a window into conflict over policy under federalism. We emphasize the importance of the strategic interaction between local and federal levels, and propose a framework to disentangle the roles of selection, local, and federal enforcement efforts, as drivers of the variation in immigration enforcement outcomes. We do this by exploiting the institutional details of the immigration enforcement process. Our strategy relies on rich data from the Secure Communities program, describing the pipeline taking unlawfully present immigrants arrested by local law enforcement into ICE custody and eventually deportation. We find strong evidence of strategic substitutabilities in the response of the local level (county) to changes in federal-level immigration enforcement, particularly among the most Democratic counties. We also find that a large fraction of the variation in the observed changes in the outcomes of immigration enforcement, such as the rates at which individuals are handed into ICE custody and are deported, are driven by changes in the composition of the pool of individuals entering into the enforcement pipeline. ICE is very effective at directing its enforcement efforts towards counties where it can expect local collaboration (possibly because of the considerable informational advantage it acquired under Secure Communities). Subsequent research should be directed at understanding the drivers of federal-level preferences over immigration outcomes.

A.1 Proof of Proposition 1

Given a vector of observables $\mathbf{w} = (x_1, x_2, x_3, y_1, y_2)$, where $x_1 > x_2 > x_3 > 0$ and $y_1 > y_2 > 0$, the following is the exhaustive list of constraints on observed probabilities:

\[
\begin{align*}
0 < g < 1 & \quad 0 < f < 1 & \quad 0 < q^f < 1 & \quad 0 < q^h < 1 \\
0 < k < 1 & \quad 0 < v^d < 1 & \quad 0 < \pi_{Hf} < 1 & \quad 0 < \pi_{Hh} < 1
\end{align*}
\]

The immigration enforcement process also implies:

\[
g = \frac{x_3 - x_2 q^h}{x_3 - x_2 q^f - x_1 (q^h - q^f)} \quad (A.1)
\]

\[
k = \frac{(x_2 - x_1 g)(y_1 q^h - y_2)}{(x_1 - x_2)(y_2 - y_1 q^f)} \quad (A.2)
\]

\[
v^d \left( \frac{1 - f}{f} \right) = \frac{(1 - x_1)(1 - g) y_2 - y_1 q^f}{x_2 - x_1 g} \quad (A.3)
\]

Beginning with $g > 0$, from equation (A.1) we have two possible cases:

Case Ia: $x_3 - x_2 q^h > 0$ and $x_3 - x_2 q^f - x_1 (q^h - q^f) > 0$, or

Case Ib: $x_3 - x_2 q^h < 0$ and $x_3 - x_2 q^f - x_1 (q^h - q^f) < 0$.

Under Case Ia,

$q^h < \frac{x_3}{x_2}$ and $q^f > \frac{x_3}{x_2 - x_1} + \frac{x_1}{x_1 - x_2} q^h$

Under Case Ib,

$q^h > \frac{x_3}{x_2}$ and $q^f < \frac{x_3}{x_2 - x_1} + \frac{x_1}{x_1 - x_2} q^h$

From $g < 1$, equation (A.1) implies two possible cases:

Case IIa: $q^h < \frac{x_3}{x_2}$ and $q^f > \frac{x_3}{x_2 - x_1} + \frac{x_1}{x_1 - x_2} q^h$ and $q^h < q^f$, or

Case IIb: $q^f < \frac{x_3}{x_2 - x_1} + \frac{x_1}{x_1 - x_2} q^h$ and $q^h > q^f$.

Now we turn to $k > 0$ which, together with equation (A.2) yields four possible cases:

Case IIIa: $x_2 - x_1 g > 0$ and $y_1 q^h - y_2 > 0$ and $y_2 - y_1 q^f > 0$, or

Case IIIb: $x_2 - x_1 g > 0$ and $y_1 q^h - y_2 < 0$ and $y_2 - y_1 q^f < 0$, or

Case IIIc: $x_2 - x_1 g < 0$ and $y_1 q^h - y_2 < 0$ and $y_2 - y_1 q^f > 0$, or

Case IIIId: $x_2 - x_1 g < 0$ and $y_1 q^h - y_2 > 0$ and $y_2 - y_1 q^f < 0$.

Under Case IIIa,

$g < \frac{x_2}{x_1}$ and $q^h > \frac{y_2}{y_1}$ and $q^f < \frac{y_2}{y_1}$.
Under Case IIIb,
\[ g < \frac{x_2}{x_1} \text{ and } q^h < \frac{y_2}{y_1} \text{ and } q^\ell > \frac{y_2}{y_1} \]

Under Case IIIc,
\[ g > \frac{x_2}{x_1} \text{ and } q^h < \frac{y_2}{y_1} \text{ and } q^\ell < \frac{y_2}{y_1} \]

Under Case IIIId,
\[ g > \frac{x_2}{x_1} \text{ and } q^h > \frac{y_2}{y_1} \text{ and } q^\ell > \frac{y_2}{y_1} \]

From \( k < 1 \) together with equation (A.2), we have four cases:

**Case IVa:** Same constraints as in Case IIIa, which imply
\[ g > \frac{x_2}{x_1} - \frac{x_1 - x_2}{x_1} \frac{y_2 - y_1 q^\ell}{y_1 q^h - y_2} \]
where the second term in the right-hand side is positive.

**Case IVb:** Same constraints as in Case IIIb, which imply
\[ g > \frac{x_2}{x_1} - \frac{x_1 - x_2}{x_1} \frac{y_2 - y_1 q^\ell}{y_1 q^h - y_2} \]
where the second term in the right-hand side is positive.

**Case IVc:** Same constraints as in Case IIIc, which imply
\[ g < \frac{x_2}{x_1} - \frac{x_1 - x_2}{x_1} \frac{y_2 - y_1 q^\ell}{y_1 q^h - y_2} \]
where the second term in the right-hand side is negative.

**Case IVd:** Same constraints as in Case IIIId, which imply
\[ g < \frac{x_2}{x_1} - \frac{x_1 - x_2}{x_1} \frac{y_2 - y_1 q^\ell}{y_1 q^h - y_2} \]
where the second term in the right-hand side is negative.

Now we turn to equation (A.3). Together with \( 0 < f < 1 \) and \( 0 < v^d < 1 \), it implies four possible cases:

**Case Va:**
\[ g < \frac{x_2}{x_1} \text{ and } q^\ell < \frac{y_2}{y_1} \text{ and } q^h > q^\ell, \text{ or} \]

**Case Vb:**
\[ g < \frac{x_2}{x_1} \text{ and } q^\ell > \frac{y_2}{y_1} \text{ and } q^h < q^\ell, \text{ or} \]

**Case Vc:**
\[ g > \frac{x_2}{x_1} \text{ and } q^\ell > \frac{y_2}{y_1} \text{ and } q^h > q^\ell, \text{ or} \]

**Case Vd:**
\[ g > \frac{x_2}{x_1} \text{ and } q^\ell < \frac{y_2}{y_1} \text{ and } q^h < q^\ell. \text{ or} \]

Collecting cases II, IV, and V, we have four possible regions in \((q^h, q^\ell)\) space with corresponding ranges for \( g \):

**Region I:**
\[ I = \left\{ (q^h, q^\ell, g) : q^h \in \left[ 0, \frac{y_2}{y_1} \right], q^\ell \in \left[ \frac{y_2}{y_1}, 1 \right], g \in \left( \frac{x_2}{x_1} - \frac{x_1 - x_2}{x_1} \frac{y_2 - y_1 q^\ell}{y_1 q^h - y_2}, \frac{x_2}{x_1} \right) \right\} \]
Equation (8), it follows that

This rules out regions II and III.

Similarly, if \( q \) attains this lower bound for any \( g \),

which gives two other cases:

Region III:

\[
III = \left\{ (q^h, q^\ell, g) : q^h \in \left[ \frac{y_2}{y_1}, 1 \right], q^\ell \in \left[ \frac{y_2}{y_1}, 1 \right], q^h > q^\ell, g \in \left( \frac{x_2}{x_1} \frac{x_2}{x_1} - \frac{x_1 - x_2 y_2 - y_1 q^\ell}{x_1 y_1 q^h - y_2} \right) \right\}
\]

Region IV:

\[
IV = \left\{ (q^h, q^\ell, g) : q^h \in \left[ 0, \frac{y_2}{y_1} \right], q^\ell \in \left[ 0, \frac{y_2}{y_1} \right], q^h < q^\ell, g \in \left( \frac{x_2}{x_1} \frac{x_2}{x_1} - \frac{x_1 - x_2 y_2 - y_1 q^\ell}{x_1 y_1 q^h - y_2} \right) \right\}
\]

Now we can turn to \( 0 < \pi^{H \ell} < 1 \) and \( 0 < \pi^{H h} < 1 \). Together these imply that \( \pi^{H h} / \pi^{H \ell} > 0 \). From equation (8), it follows that

\[ g < \frac{x_2}{x_1} \]

This rules out regions II and III.

From equation (9), we have two cases:

Case VIa:

\[ q^\ell < \frac{x_3}{x_2} \text{ and } q^h > \frac{x_3}{x_2}, \text{ or} \]

Case VIIb:

\[ q^\ell > \frac{x_3}{x_2} \text{ and } q^h < \frac{x_3}{x_2}, \text{ or} \]

From equation (8), we have that

\[ \frac{\pi^{H h}}{\pi^{H \ell}} = \frac{y_1 q^\ell - y_2}{y_2 - y_1 q^h} k \]

which gives two other cases:

Case VIIa:

\[ q^\ell > \frac{y_2}{y_1} \text{ and } q^h < \frac{y_2}{y_1}, \text{ or} \]

Case VIIb:

\[ q^\ell < \frac{y_2}{y_1} \text{ and } q^h > \frac{y_2}{y_1}, \text{ or} \]

Collecting cases VI and VII together, we have two regions for \((q^h, q^\ell)\):

Region R1:

\[ R_1 = \left\{ (q^h, q^\ell) : q^h < \min \left\{ \frac{x_3}{x_2}, \frac{y_2}{y_1} \right\}, \text{ and } q^\ell > \max \left\{ \frac{x_3}{x_2}, \frac{y_2}{y_1} \right\} \right\} \]

Region R2:

\[ R_2 = \left\{ (q^h, q^\ell) : q^h > \max \left\{ \frac{x_3}{x_2}, \frac{y_2}{y_1} \right\}, \text{ and } q^\ell < \min \left\{ \frac{x_3}{x_2}, \frac{y_2}{y_1} \right\} \right\} \]

Notice that the constraints from Cases I and II become redundant relative to the regions defined by \( R_1 \) and \( R_2 \).

Since we have ruled out regions II and III, it follows that \( g > \frac{x_2}{x_1} - \frac{x_1 - x_2 y_2 - y_1 q^\ell}{y_1 (x_1 - x_2)} \). From equation (A.1), and \( g > 0 \), we have that if \( q^h < \frac{x_2}{x_1} \), then \( x_3 - x_2 q^\ell - x_1 (q^h - q^\ell) > 0 \). In this case, after some algebra it follows that \( g \) attains this lower bound for any

\[ q^\ell > \frac{x_1 y_2 - x_3 y_1}{y_1 (x_1 - x_2)}. \]

Similarly, if \( q^h > \frac{x_2}{x_1} \), then \( x_3 - x_2 q^\ell - x_1 (q^h - q^\ell) < 0 \), in which case \( g \) attains this lower bound for any

\[ q^\ell < \frac{x_1 y_2 - x_3 y_1}{y_1 (x_1 - x_2)}. \]
This, together with $R_1$ and $R_2$ gives us

$$R_1 = \left\{ (q^h, q^f) : q^h < \min \left\{ \frac{x_3}{x_2}, \frac{y_2}{y_1} \right\}, \text{ and } q^f > \max \left\{ \frac{x_3}{x_2}, \frac{y_2 - x_3 y_1}{y_1(x_1 - x_2)} \right\} \right\}$$

and

$$R_2 = \left\{ (q^h, q^f) : q^h > \max \left\{ \frac{x_3}{x_2}, \frac{y_2}{y_1} \right\}, \text{ and } q^f < \min \left\{ \frac{x_3}{x_2}, \frac{y_2 - x_3 y_1}{y_1(x_1 - x_2)} \right\} \right\}$$

so the identified set for $(q^h, q^f)$ is given by $R = R_1 \cup R_2$. Notice that for any $(q^h, q^f) \in R$, the implied values for $g$ and $k$ are always valid probabilities, and $v^d(1 - f)/f > 0$, and $g > \frac{x_2}{x_1} - \frac{x_1 - x_2}{x_1} \frac{y_2 - y^f}{y_1 q^h - y_2}$.

#### A.2 Inference for the coefficients in equations (19) and (20)

In equations (19) and (20), $\epsilon_{ct}$ and $\xi_{ct}$ are generated regressors because these residuals are recovered using not the true $(\delta^d, \beta^f, \beta^g)$ coefficients from equations (17) and (18), but estimates of these coefficients. Thus, we must account for the sampling variation induced by our use of estimates of $\epsilon_{ct}$ and $\xi_{ct}$ on the variance of the estimator for $(\beta^h, \kappa_{ct}, \kappa_{ct}, \beta^f, \gamma^f)$. Our derivation closely follows (Wooldridge, 2002, p. 139-141). We present below the derivation of the variance-covariance matrix for the OLS estimator of the coefficients in equation (19) only. The corresponding derivation for the OLS estimator of the coefficients in equation (20) is analogous, only simpler because while equation (19) has two generated regressors, equation (20) only has one generated regressor. Consider the log-odds equation

$$\tilde{k}_{ct} = x_c^* \beta + \kappa_c \epsilon_{ct} + \kappa_{ct} \xi_{ct} + \eta_{ct}$$

with $\text{dim}(x_c) = K$, and re-write it as

$$\tilde{k}_{ct} = x_c^* \beta + \eta_{ct}$$

where $x_c^* \equiv [x_c, \xi_{ct}, \epsilon_{ct}]$, and $\beta \equiv [\beta^f, \kappa_{ct}, \kappa_c]'$. Using equations (18) and (21), we can now notice that $x_c^* = \mathcal{F}(z_{ct}, \delta)$, where

$$\mathcal{F}(z_{ct}, \delta) = z_{ct} \Delta(\delta)$$

where $\delta \equiv [\delta^d - \beta^f, -\beta^g]'$, $z_{ct} \equiv [x_c, v^d_{ct}, f, \tilde{g}]$, $v^d_{ct} \equiv (0, ..., 1, ..., 0)$ is a vector of dimensions $1 \times D$ where $D$ is the number of federal districts minus one that has a 1 in the column corresponding to the district that county $c$ belongs to, and

$$\Delta(\delta) \equiv \begin{bmatrix} I_{K \times K} & -\beta^f & -\beta^g \\ 0_{D \times 1} & \delta^d & 0_{D \times 1} \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}$$

Define $T_c$ as the number of time periods available for county $c$, and thus $N = \sum_{c} T_c$ as the total number of observations. We have a $\sqrt{N}$ consistent estimator of $\delta$, namely $\hat{\delta} = [\hat{\delta}^d_{OLS}, -\hat{\beta}^f_{OLS}, -\hat{\beta}^g_{OLS}]$, where

$$\begin{bmatrix} \delta^d_{OLS} \\ \beta^f_{OLS} \end{bmatrix} = \left( \sum x_c^r x_c^r \right)^{-1} \left( \sum x_c^r f_{ct} \right)$$

and

$$\hat{\beta}^g_{OLS} = \left( \sum x_c^r x_c^r \right)^{-1} \left( \sum x_c^r \tilde{g}_{ct} \right).$$

We do not observe the $x_c^r$ because we do not observe $\delta$. However, we have a consistent estimate of $\delta$, namely $\hat{\delta}$, so we can compute

$$\hat{x}_c^r = \mathcal{F}(z_{ct}, \hat{\delta}).$$

It is these $\hat{x}_c^r$ we use to estimate $\beta$ in the regression equation for $\tilde{k}_{ct}$. Our OLS estimator for $\beta$ is

$$\hat{\beta} = \left( \sum \hat{x}_c^r \hat{x}_c^r \right)^{-1} \left( \sum \hat{x}_c^r \hat{k}_{ct} \right).$$
We can re-write equation (A.4) as
\[ \hat{k}_{ct} = \hat{x}_c^* \beta + (x_c^* - \hat{x}_c^*) \beta + \eta_{ct} \]
and replace it above to obtain
\[ \hat{\beta} = \beta + \left( \sum \hat{x}_c^* \hat{x}_c^* \right)^{-1} \left( \sum \hat{x}_c^* (x_c^* - \hat{x}_c^*) \beta + \sum \hat{x}_c^* \eta_{ct} \right) \]
Thus,
\[ \sqrt{N}(\hat{\beta} - \beta) = \left( N^{-1} \sum \hat{x}_c^* \hat{x}_c^* \right)^{-1} \left( N^{-1/2} \sum \hat{x}_c^* (x_c^* - \hat{x}_c^*) \beta + N^{-1/2} \sum \hat{x}_c^* \eta_{ct} \right) \]
Notice that
\[ \hat{\mathcal{C}} \equiv N^{-1} \sum \hat{x}_c^* \hat{x}_c^* \rightarrow^p E[\hat{x}_c^* \hat{x}_c^*] \]
and
\[ N^{-1/2} \sum \hat{x}_c^* \eta_{ct} = N^{-1/2} \sum x_c^* \eta_{ct} + o_p(1) \]
The remaining term can be expressed as
\[ N^{-1/2} \sum \hat{x}_c^* (x_c^* - \hat{x}_c^*) \beta = - \left[ N^{-1} \sum (\beta \otimes x_c^*)' \nabla \delta \mathcal{F}(z_{ct}, \delta) \right] \sqrt{N}(\hat{\delta} - \delta) + o_p(1) \]
Defining \( \mathbf{G} \equiv E[(\beta \otimes x_c^*)' \nabla \delta \mathcal{F}(z_{ct}, \delta)] \), we have that
\[ N^{-1/2} \sum \hat{x}_c^* (x_c^* - \hat{x}_c^*) \beta = - \mathbf{G} \sqrt{N}(\hat{\delta} - \delta) + o_p(1) \]
Finally, the term \( \sqrt{N}(\hat{\delta} - \delta) \) can be expressed as
\[ \sqrt{N}(\hat{\delta} - \delta) = \sqrt{N} \left[ \begin{array} \delta^d_{OLS} \\ \hat{\delta} \end{array} \right] - \left[ \begin{array} \delta^d \\ \beta \end{array} \right] = N^{-1/2} \left[ \begin{array} A_f^{-1} & 0_{(D+K) \times K} \\ 0_{K \times (D+K)} & A_g^{-1} \end{array} \right] \left[ \begin{array} -x_{ct}^* \xi_{ct} \\ x_{ct}^* \xi_{ct} \end{array} \right] + o_p(1) \]
where \( A_f \equiv (N^{-1} \sum x_{ct}^* x_{ct}^*) \) and \( A_g \equiv (N^{-1} \sum x_{ct} x_{ct}) \). Thus, we can define
\[ \mathbf{r}_{ct}(\delta) \equiv \left[ \begin{array} A_f^{-1} & 0_{(D+K) \times K} \\ 0_{K \times (D+K)} & A_g^{-1} \end{array} \right] \left[ \begin{array} -x_{ct}^* \xi_{ct} \\ x_{ct}^* \xi_{ct} \end{array} \right] \]
and hence
\[ \sqrt{N}(\hat{\beta} - \beta) = C^{-1} \left\{ N^{-1/2} \sum x_{ct}^* \eta_{ct} - \mathbf{G} \mathbf{r}_{ct}(\delta) \right\} + o_p(1) \]
The Central Limit Theorem implies that
\[ \sqrt{N}(\hat{\beta} - \beta) \sim N(0, C^{-1} \mathbf{M} C^{-1}) \]
where \( \mathbf{M} \equiv \text{Var}(x_{ct}^* \eta_{ct} - \mathbf{G} \mathbf{r}_{ct}(\delta)) \). A consistent estimator for this asymptotic variance is given by \( (\hat{\mathcal{C}}^{-1} \hat{\mathbf{M}} \hat{\mathcal{C}}^{-1})/N \), where
\[ \hat{\mathbf{M}} = N^{-1} \sum (\hat{x}_c^* \hat{\eta}_{ct} - \hat{\mathbf{G}} \hat{\mathbf{r}}_{ct})(\hat{x}_c^* \hat{\eta}_{ct} - \hat{\mathbf{G}} \hat{\mathbf{r}}_{ct})', \]
\[ \hat{\mathbf{G}} = N^{-1} \sum (\hat{\beta} \otimes \hat{x}_c^*)' \nabla \delta \mathcal{F}(z_{ct}, \hat{\delta}), \]
\[ \hat{\mathbf{r}}_{ct} = \hat{\mathbf{r}}_{ct}(\hat{\delta}), \]
and
\[ \hat{\eta}_{ct} = \hat{k} - \hat{x}_c^* \hat{\beta}. \]
A.3 Identification of the Percent Difference in Removals under the Counterfactual of no Change in the Enforcement Guidelines

Here we show that under Secure Communities, the percent difference in the number of removals between the model predictions based on our estimates and the counterfactual prediction in the absence of a change in the enforcement guidelines is point identified for every county-period.

The number of removals can be expressed as the number of fingerprint matches (arrests of unlawfully present immigrants) times the unconditional removal probability $P(\text{Removal})$. In turn, $P(\text{Removal})$ can be expressed as

$$P(\text{Removal}) = P(\text{Detainer})P(\text{ICE Custody}\mid \text{Detainer})P(\text{Removal}\mid \text{ICE Custody, Detainer})$$

$$+ (1 - P(\text{Detainer}))P(\text{ICE Custody}\mid \text{No Detainer})P(\text{Removal}\mid \text{ICE Custody, No Detainer})$$

$$= (q^g \pi^{H^l} + q^h \pi^{Hh}) f + (1 - P(\text{Detainer}))v^d \frac{1 - f}{1 - P(\text{Detainer})}(q^f k \pi^{H^l} + q^h \pi^{Hh})$$

While $\pi^{H^l}$ is not identified, the expression inside curly brackets depends only on identified quantities. Define $A(\epsilon, \xi)$ as the expression inside curly brackets. The percent difference in the number of removals in a given county period between the model predicted and the counterfactual scenario is given by:

$$\text{% difference} = \frac{\text{Removals counterfactual} - \text{Removals predicted}}{\text{Removals predicted}}$$

$$= \pi^{H^l} A(\hat{\epsilon}^{\text{count}}, \hat{\xi}^{\text{count}}) - \pi^{H^l} A(\hat{\epsilon}^{\text{pred}}, \hat{\xi}^{\text{pred}})$$

$$= A(\hat{\epsilon}^{\text{count}}, \hat{\xi}^{\text{count}}) - A(\hat{\epsilon}^{\text{pred}}, \hat{\xi}^{\text{pred}})$$

which depends only on identified quantities.

We can similarly recover the counterfactual aggregate percentage change in removals for all counties in our sample by letting predicted removals be equal to removals observed in the data. We also assume that the number of arrests $M$ (fingerprint matches) is the same in the counterfactual. Then the percentage change in removals is

$$\sum_i \hat{M}_i A(\hat{\epsilon}^{\text{count}}, \hat{\xi}^{\text{count}}) \pi^{H^l}_i - \sum_i \hat{M}_i A(\hat{\epsilon}^{\text{pred}}, \hat{\xi}^{\text{pred}}) \pi^{H^l}_i - 1$$

where $i$ is a county-period. Now, assuming the model-predicted deportation rate is equal to the observed deportation rate, $\hat{\delta}$, we obtain $\pi^{H^l}_i = \hat{\delta} / A(\hat{\epsilon}^{\text{pred}}, \hat{\xi}^{\text{pred}})$, which lets us express the change in removals as a function of observable quantities:

$$\sum_i \hat{M}_i A(\hat{\epsilon}^{\text{count}}, \hat{\xi}^{\text{count}}) \hat{\delta}^i - \sum_i \hat{M}_i \hat{\delta}^i$$

We can then recover the type-$s$ (e.g. assaults) percentage change in removals as

$$\sum_i \hat{\alpha}_{is} \hat{M}_i A(\hat{\epsilon}^{\text{count}}, \hat{\xi}^{\text{count}}) \hat{\delta}^i - \sum_i \hat{\alpha}_{is} \hat{M}_i \hat{\delta}^i$$

where $\hat{\alpha}_{is}$ is the share of type-$s$ removals in county period $i$.

B  Online Appendix B: Additional Figures and Tables

![Figure B.1: County Rollout of Secure Communities Activation.](image)

The figure shows the yearly (solid line) and cumulative (dashed line) number of counties activated for Secure Communities (source: Cox and Miles (2013)).
Figure B.2: Immigration and Customs Enforcement Federal Immigration Districts. The figure shows the geographic boundaries of the 24 ICE federal immigration districts and their corresponding headquarters. Source: ICE.
Figure B.3: Example identified set for \((q^h, q^\ell)\). The figure shows the identified set for \((q^h, q^\ell)\) from a sample observation. The top left rectangle is \(R_1\). The bottom right rectangle is \(R_2\). The color shade represents the value of the implied \(g\), with higher values of \(g\) represented by warmer colors and lower values of \(g\) represented by cooler colors. Dark blue represents the region outside the identified set.
Figure B.4: Counties in the Model Estimation Sample. The map highlights the counties (in lavender) and the CBSA's (in blue) included in the sample used to estimate the model of the immigration enforcement process.
Figure B.5: Scatterplot of Actual vs Counterfactual Federal Efforts. Panel (a) shows a scatterplot of predicted (x-axis) and counterfactual (y-axis) federal immigration enforcement efforts $\xi^m$ for arrestees charged with minor (levels 2-4) offenses. Panel (b) shows a scatterplot of predicted (x-axis) and counterfactual (y-axis) federal immigration enforcement efforts $\xi^s$ for arrestees charged with serious (level 1) offenses. The counterfactual exercise simulates no federal policy guidelines change after 2011-II.

Figure B.6: Distribution of Percent Changes in Removals: No Change in Guidelines Counterfactual vs. Baseline Prediction. Panel (a) shows a histogram of the distribution across county-time periods of percent changes in removals for minor (levels 2-4) offenses, between the no change in guidelines counterfactual and the baseline prediction based on the model estimates. Panel (b) shows a histogram of the distribution across county-time periods of percent changes in removals for serious (level 1) offenses, between the no change in guidelines counterfactual and the baseline prediction based on the model estimates.
### Table B.1: Descriptive Statistics for Immigration Enforcement Variables.

The table presents summary statistics for the variables related to the immigration enforcement process under Secure Communities. We report counts of events aggregated at the county-semester level of observation. All variables in panels A and B refer to minor offenses (level 2-4 under ICE’s classification). All variables in panels C and D refer to serious offenses (level 1 under ICE’s classification). Panels A and C report summary statistics from 2009-I to 2011-I (before the June 2011 policy guidelines change). Panels B and D report summary statistics from 2011-II to 2014-II (after the June 2011 policy guidelines change). Arrests are measured as the number of fingerprint matches under Secure Communities. Our source for arrests, detainers, and ICE custodies is a FOIA to DHS. Our source for removals and for classifying ICE custodies between those with and without detainers is TRAC.
### Panel A: All counties above median undocumented share

**Table B.2: Descriptive Statistics for the County Sample.** The table presents summary statistics of the county characteristics of our sample of counties. Panel A reports summary statistics for all counties with undocumented population above median. Panel B reports summary statistics for all counties above median undocumented population that satisfy the conditions required for estimation of the immigration enforcement process model. Log Population is taken from the 2010 Census. Undocumented share is an estimate of the number of unlawfully present individuals in 2010 (its construction is described in Appendix C). Democratic party share is an average of the 2008 and 2012 Democratic Presidential vote shares, taken from David Leip’s Electoral Atlas. Bachelor degree share is measured as the fraction of the adult population with at least a bachelor’s degree. Hispanic share is measured as the fraction of the population who is hispanic. Services share is measured as the fraction of the employed population working in the services sector. Bachelor degree share, Hispanic share, and Services share are taken from the 2006-2010 waves of the American Communities Survey. Rural is a dummy variable indicating whether the county is considered non-metropolitan according to the National Center for Health Statistics at the Center for Disease Control. Distance to ICE office is measured as the log of the number of miles between the county centroid and the county centroid of the corresponding ICE district office seat, and computed directly by us. 287(g) Program is a dummy variable indicating whether the county or any city in the county was ever part of the 287(g) program, taken from Steil and Vasi (2014).
Table B.3: Correlation Matrix of Enforcement Efforts and Preference Alignment. The table shows the correlation matrix of selected enforcement variables. Panel A shows the correlation coefficients for minor offenses while panel B shows the coefficients for serious offenses.

Table B.5: Coefficients on the covariates of the logistic regressions for the enforcement probabilities. Minor Offenses. The table reports the $\beta$ coefficients for the logistic regressions in equations (17)-(20) for minor offenses. Democratic party share is an average of the 2008 and 2012 Democratic Presidential vote shares minus 50 percent, taken from David Leip’s Electoral Atlas. Bachelor degree share is measured as the fraction of the adult population with at least a bachelor’s degree. Hispanic share is measured as the fraction of the population who is Hispanic. Bachelor degree share and Hispanic share are taken from the 2006-2010 waves of the American Communities Survey. Guidelines is a dummy variable indicating the semesters after the policy guidelines change under the Obama administration. Mexican share is the fraction of detainers issued against unlawfully present Mexican nationals in a given county-semester. Central American share is the fraction of detainers issued against unlawfully present Central American nationals in a given county-semester. Young share is the fraction of detainers issued against unlawfully present immigrants less than 30 years old. The Mexican, Central American and Young shares are taken from the TRAC detainers dataset. 911 calls is the log of the total number of calls to the emergency number 911 at the county-year level. Standard errors are robust to arbitrary heteroskedasticity.
### Table B.6: Coefficients on the covariates of the logistic regressions for the enforcement probabilities. Serious Offenses.

The table reports the $\beta$ coefficients for the logistic regressions in equations (17)- (20) for serious offenses. Democratic party share is an average of the 2008 and 2012 Democratic Presidential vote shares minus 50 percent, taken from David Leip’s Electoral Atlas. Bachelor degree share is measured as the fraction of the adult population with at least a bachelor’s degree. Hispanic share is measured as the fraction of the population who is hispanic. C Online Appendix C: Construction of Variables

C.1 Undocumented Share

We use different sources to construct estimates of the undocumented population at the county level. Warren and Warren (2012), Passel (2005) and the Department of Homeland Security provide estimates of the undocumented population at the state level for different years and use a residual method that combine the number of people entered in the US and the number of non citizens from Census and other survey data. Estimates at substate level are almost nonexistent. One exception is Hill and Johnson (2011), who use information from tax returns to estimate the undocumented population at the county and at the zip-code levels in California. Since 1996, unauthorized immigrants, who lack social security numbers, have been allowed to file federal tax returns using a unique identifier, the Individual Taxpayer Identification Number, or ITIN. Hill and Johnson (2011) show that this measure is highly correlated with the estimates of undocumented population at the state level. This is not surprising; although many undocumented immigrants lack a social security number, they still have an incentive to file taxes in order to collect tax refunds. Our preferred measure of the undocumented population combines the number of Hispanic non citizens from the ACS, the state level estimates from Warren and Warren (2012), and the number of ITIN filers.

\[
\text{undocumented}_{\text{county}} = \text{undocumented}_{\text{state2010}} \times \frac{1}{2} \left( \frac{\text{hisp noncitizens}_{\text{county}}}{\text{hisp noncitizens}_{\text{state2010}}} + \frac{\text{ITIN}_{\text{county}}}{\text{ITIN}_{\text{state2010}}} \right)
\]

C.2 Consistency between Model and Data

C.2.1 Assigning ICE Arrests to Detainer or Direct Track

Secure Communities data on ICE arrests (custodies) do not have information on whether a detainer was issued or not. To identify custodies from detainers, we use detainers data from TRAC on the universe of detainers, which include detainers on SC as well as other detainers. TRAC detainers data include information on whether the individual ended up in ICE custody and we can apply the custody-detainer ratio to the SC detainers to recover the number of custodies from SC detainers under the assumption that SC detainers and overall detainers have a similar composition. To avoid inconsistencies in the arrests and removals data between both sources (TRAC and Secure Communities), we define \( p \) as the constant such that \( C = Dp + (M - D)p = Mp \), where \( C \) is ICE custodies, \( D \) is detainers and \( M \) is local arrests. \( p \) is the probability that an immigrant is taken into ICE custody if the probability is the same along the detainer and the direct tracks. It follows that

\[
C = D \left( p + \frac{M - D}{M} \right) + (M - D) \left( p - \frac{D}{M} \right)
\]

Now, \( \epsilon \) allows the probabilities to differ across tracks, while keeping them consistent with the observed \( C \). The idea is to make \( \epsilon \) increasing in the custody-detainer ratio from TRAC: \( s \equiv \frac{C(n_D - D)}{D(n_D - C)} \). Using the restrictions that \( p_1, p_2 \in [0,1] \) we can recover a lower bound \( \xi \) and an upper bound \( \eta \). Additionally, we can impose the restrictions \( R|D|C|D \) and \( R|\text{noD}|C|\text{noD} \) to construct the two bounds for \( \epsilon \). Then, we can set \( \epsilon = (1 - s)\xi + s\eta \) where the lower bound is \( \xi = \max \{-C/(M - D), -(M - C)/D, -(C - R|D|M/D)/(M - D)\} \) and the upper bound is \( \eta = \min \{C/D, (M - C)/(M - D), C/D - M \ast R|\text{noD}|/(D \ast (M - D))\} \).

C.2.2 Consolidating Counties into CBSA

Our empirical strategy puts significant demands on the data. In particular, we need positive counts at each step of the deportation process. The number of counties that satisfy these requirements is limited (650 in the sample for minor offenses). In an effort to work with a larger sample, we group neighboring counties not in the initial sample that fall into core-based statistical areas (CBSA), a census definition that includes both metropolitan statistical areas and micropolitan areas. We are able to add 19 CBSA that satisfy the requirements for our estimation strategy, assigning them covariate values computed as weighted averages of the covariates across counties within each of these CBSA’s. Figure B.4, illustrates in dark blue the CBSA’s in our sample.
