Large Macroeconomic shocks during the Pandemic: 
a DSGE analysis

ABSTRACT
This paper estimates a DSGE model including the Covid-19 episode. To let the data speak about the diverse types of macroeconomic shocks caused by the pandemic, we build a Two-Sector One (Two-Agent) model and estimate it through Bayesian methods. The resulting medium-scale New Keynesian model includes the standard real and nominal frictions used in the empirical literature and allows for heterogeneous pandemic exposure across sectors. On account of the magnitude of the involved shocks, we solve the model nonlinearly. To conduct inference on the resulting non-linear non-Gaussian system, we employ a version of the Cubature Kalman filter to handle the large shocks and use the Sequential Monte Carlo sampler to obtain parameters draws from the posterior distribution. Large shocks pose questions about the way of modeling the interdependence between them, so we use a flexible specification that allows to distinguish between all possible combinations of disaster shocks. Results show that the pandemic-induced economic downturn can be reconciled with a combination of demand and supply factors.

INTRODUCTION
The unprecedented economic losses due to the COVID-19 pandemic require to take into account nonlinearities and heterogeneity.

THE DSGE MODEL
The benchmark model is the One-Household Two-Sector model:

\[ E_0 \sum_{t=0}^\infty \beta^t a_{t,t} \left( \frac{1 - \beta_1}{1 - \beta} \log(c_{1,t} - h_{1,c_{1,t-1}}) + a_{1,t} \frac{1 - \beta_2}{1 - \beta_2} \log(v_{2,t} - h_{2,v_{2,t-1}}) - \phi_{1,t} + n_{1,t+1} \right) \]

\[ Y_{1,t} = (a_{z_{1},1} n_{1,t})^{1-\alpha_1} (u_{k_{1},1} k_{1,t-1})^{\alpha_1} \]

\[ Y_{2,t} = (a_{z_{2},1} n_{2,t})^{1-\alpha_2} (u_{k_{2},2} k_{2,t-1})^{\alpha_2} \]

Large shocks: Supply
- Labor supply \( \phi_{1,t} \phi_{2,t} \)
- Labor productivity \( a_{z_{1},1} a_{z_{2},1} \)

Large shocks: Demand
- Intratemporal preference \( a_{j,t} \)
- Intertemporal preference \( a_{\zeta,t} \)

THE FILTERING PROBLEM

\[ p(x_{t+1}^{obs}) = \left( 1 - \sum_{i \in I} \right) N(0, I) + \sum_{i \in I} p_i N(\mu_i, \Sigma_i) \cdot diag(c_i) \]

All the possible combinations of large and ordinary shocks are tested.

In addition to large shocks, nonlinearity stems from the Zero Lower Bound, which we model using a smooth nonlinear Taylor rule.

The model is solved by a second order perturbation.

26 state variables + large shocks:
A particle filter becomes hardly feasible.

We use a version of the Cubature Kalman Filter for non-Gaussian shocks: Gaussian Sum Cubature Kalman Filter.

Banks of Cubature Kalman filters run in parallel by making as many predictions as the possible number of large shocks combinations. Then ensemble weights are computed and the filters are merged.

\[ w_i = \frac{p_i(q_i, x_{t-1}) w_{i-1}}{\sum_{i=1}^{GK} p_i(q_i, x_{t-1}) w_{i-1}} \]

\[ P_{it} = \sum_{i=1}^{GK} w_{ii} \left[ (x_{it}^{*} - x_{it}) (x_{it}^{*} - x_{it})^T \right] \]

- In Engineering: Faubel et al. (2009), Leong et al. (2013).

ESTIMATION METHODOLOGY
The model is estimated with Bayesian methods.

The sequential Monte Carlo sampler (SMC) is used.

RESULTS
The filter detects the following combination of large shocks at quarter 2020.II

- Labor supply Sector 1 \( E_{t+1} \)
- Sector 2 specific demand shock \( E_{t+2} \)
- Labor productivity Sector 2 \( E_{t+3} \)
- General demand shock \( E_{t+4} \)

The standardized large shocks are depicted in the following figure:

We divide the economy into the Leisure and Hospitality sector (Sector 2) and the rest of the economy (Sector 1).

We estimate the two-sectoral model on US data up to 2020.II.
