Literature

Study	Model	Finding		
Jalan & Ravallion (2003) (Pipe Water and Child Health)	Propensity Score Matching India, NCAER 1993-94	 Diarrhea prevalence reduces by 0.023 pp with pipe water. Disease prevalence and illness duration amongst those with pipe water would be 21% & 29% lower, respectively Effect is smaller with lower mother's education 		
Choudhuri & Desai (2020) (Pipe Water and Child Education)	Random Effects-Village Level and entropy balanced OLS IHDS, 2012	 IPDW does not significantly affect study (homework) time, educational expenses and math score. With entropy balancing, a significant 10% increase in educational expense for girls, no other outcomes affected. 		
Koolwal & van deWalle (2014) (Water collection time, women's work and child schooling)	Geographic averaging with comprehensive regression controls Rural Econ. Development Survey, 1997	 1) 1 hour reduction in water collection minutes increases likelihood of wage work by 9.1% for women. 2) No significant increase in child school enrollment. 		
Kumar & Vollmer (2013) (Improved sanitation and child illness)	Propensity Score Matching District Level Household Survey, 2008	 Incidence of diarrhea with improved sanitation is 2.2 pp lower than those without improved sanitation.

Note: Panel (a) displays the average fraction of women who were at least 15 years old and participated in the labor force by country or region in the period 1990-2005 (white bar) and the period 2006-2015 (black bar). Panel (b) is analogous to Panel (a) for men. $\%\Delta$ is the percentage change between the black and white bars. Source: Author's calculations using The World Bank (2019a,b).

Author elaboration, IHDS, 2005-2012, ACCESS survey, 2015-2018. ACCESS survey is for the rural areas in the six relatively poorer states in India namely: Madhya Pradesh, Uttar Pradesh, Odisha, Bihar, Jharkhand, West Bengal. The t-test shows mean difference in access to IPDW by the year of survey, 2015 and 2018.
