## Abstract

- Individuals **infer their own health risk** after observing health experiences of their family members (e.g., new major diagnoses or hospitalizations)
- When an individual is newly diagnosed with a chronic condition:
  - Unaffected family members increase their healthcare spending by **↑ 10%**
  - Spillovers include **↑ use of both high- and low-return care**
- Responses are consistent with **individual updating of their own health risks**
- To assess welfare, I estimate a structural model of health choices with learning. I find that:
  - Consumers over-respond to events by **over-weighting ex-post risks**
  - This leads to annual welfare losses of **\$2,788 per family** on average
  - Limiting responsiveness results in net gains for **86% of households**
  - Revealing information can be optimally targeted to improve social welfare

## Results: Spillover Effects and Mechanisms

1. Diagnoses ⇒ **informational spillovers** for household members (Figure 1)
  - a. This includes **↑ in total utilization** and **↑ in preventive care**
  - b. Increases are particularly strong for **disease-specific prevention** (e.g., diabetes screenings after a new diabetes diagnosis; Figure 2a)
2. Results are **most consistent** with belief updating (*Competing Mechanisms*):
  - a. **Moral hazard**: Spending **↑** even when spot prices don't change (Figure 2b)
  - b. **Salience**: Diagnoses induce stronger preventive responses than acute events
  - c. **Health System Learning**: Even those with high health system knowledge are responsive to new household diagnoses (Figure 2c)
3. Responses include **↑ utilization of "quasi-preventive" low-value care**<sup>7</sup>
  - Cardiac screenings prior to low-risk surgery
  - Imaging services (e.g., for lower back pain)

## Introduction

### Social networks provide information for consumers' health choices

- Individual expectations of health needs are updated as they observe the experiences of **family members**, friends, and neighbors<sup>1,2</sup>
- Spillover effects may include **updated beliefs about health risk**, but also:
  - **Moral hazard**: Changes to the expected price of medical care<sup>3</sup>
  - **Salience**: Preferences for health consumption (e.g., risk aversion)<sup>4</sup>
  - **Health System Information**: Knowledge about the availability of services<sup>5</sup>

### Data and Setting

- Nuclear households with employer-sponsored insurance (ESI), 2006-2018
- Setting: new diagnoses of chronic conditions (e.g., diabetes, depression, asthma)

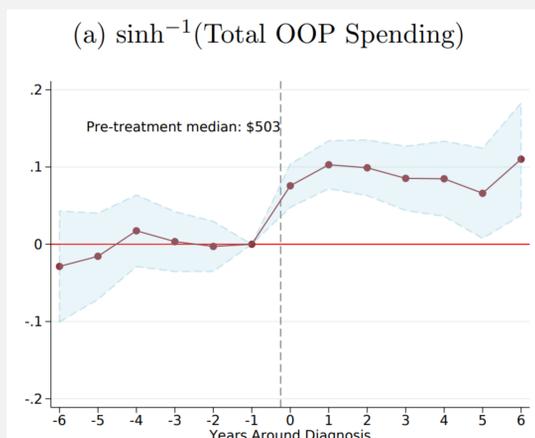

Figure 1. Households increase spending by ~10% in response to intra-household health events

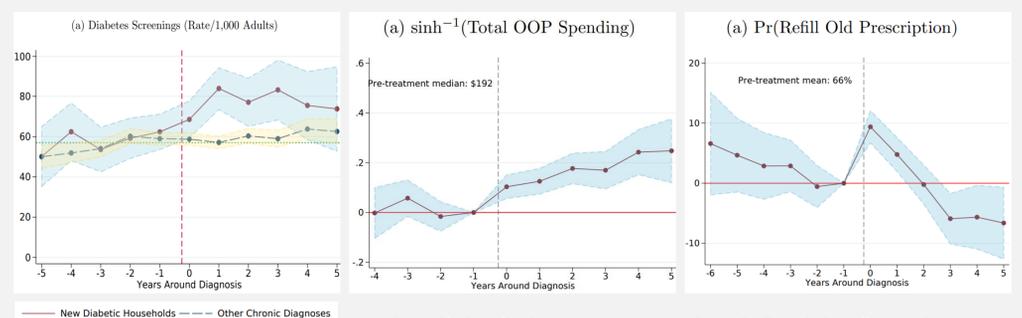

Figure 2a. ↑ in Disease-specific screenings

Figure 2b. Spending increases even for those in zero-deductible plans

Figure 2c. Prescription adherence increases even for those most at risk prior to event

## Results: Belief Evolution

1. New information is **not welfare-improving** for >90% of households
  - a. New information lowers expected utility by an average of **\$2,788 per year**
2. There is a tension between **an event's seriousness** and **correct updating**:
  - a. Diagnoses spur overly large changes in beliefs about risk (Figure 3)

### Counterfactual Simulations

1. Bounding changes in risk beliefs would substantially increase consumer welfare
  - a. **86% of households** would find information welfare-improving
2. Targeting risk information to **highest-risk** individuals further improves returns

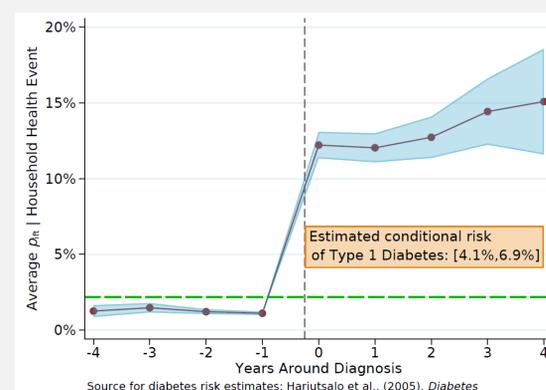

Figure 3. New diagnoses lead to substantial over-updating of household beliefs about risk

## Methods and Contributions

### Reduced-Form Evidence: Spillovers and Mechanisms

- I identify **causal** impact of health shocks on choices using TWFE regressions:

$$\sinh^{-1}(y_{ft}) = \alpha_f + \tau_t + \sum_{k=-T}^T \gamma_k \mathbb{I}\{t - E_{ft} = k\} + \varepsilon_{ft}$$

- Results are robust to alternative TWFE estimators
- Explore effects on competing mechanisms based on selection of  $y_{ft}$

### Structural Approach: Belief Evolution and Learning

- Model where **households form beliefs** about their health risks over time
- Households choose insurance plan, then select health care in response to fluctuations in individual health states
- Health events ⇒ **updated beliefs**, but also updated **spot prices** and **risk aversion**

### Structural Identification:

- Variation in treatment costs identifies spot price changes (moral hazard)
- Plan choice set variation identifies household risk aversion<sup>6</sup>
- Characteristics of diagnostic event **identify belief evolution separately**

## Conclusions & Contributions

### Health information ⇒ powerful spillover effects in family networks

1. **Novel (strong!) channel** for health spillovers: **chronic diagnoses**
2. **Mechanisms**: health events affect decisions **most** by how they affect beliefs
3. **Heterogeneous Returns**: diagnoses increase use of **both high and low-value** care, ultimately resulting in **welfare losses** for the average household

### Other Contributions

- Learning and preferences in structural models of health behavior<sup>8</sup>
- Non-Bayesian learning, with an emphasis on salience of recent events
- Suboptimal health decisions made by many health consumers<sup>9</sup>
